The Journal

OF THE

American Medical Association

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES BY

MORRIS FISHBEIN, M.D.

VOLUME 99 JULY—DECEMBER, 1932

AMERICAN MEDICAL ASSOCIATION, CHICAGO, 1932

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1932-1933

OF THE ASSOCIATION, 535 N. DEARBORN ST., CHICAGO

GENERAL OFFICERS

PRESIDENT—E. H. CARY	Dallas, Texas
PRESIDENT-ELECT—DEAN LEWIS	Baltimore
VICE PRESIDENT—RUDOLPH MATAS	New Orleans
SECRETARY AND GENERAL MANAGER—OLIN WEST	Chicago
TREASURER—AUSTIN A. HAYDEN	Chicago
SPEAKER, HOUSE OF DELEGATES—F. C. WARNSHUIS	Grand Rapids, Mich.
VICE SPEAKER, HOUSE OF DELEGATES—ALBERT E. BULSON *	Fort Wayne, Ind.
EDITOR AND GENERAL MANAGER EMERITUS—GEORGE H. SIMMONS	Chicago
EDITOR—MORRIS FISHBEIN	Chicago
BUSINESS MANAGER—WILL C. BRAUN	Chicago

BOARD OF TRUSTEES

J. H. Walsh, Secretary	Chicago,	1933
A. R. Mitchell, Chairman	Lincoln, Neb.,	1933
D. Chester Brown	Danbury, Conn.,	1934
Allen H. Bunce	Atlanta, Ga.,	1934
Joseph A. Pettit	Portland, Ore.,	1935
J. H. J. Upham	Columbus, Ohio,	1935
Thomas S. Cullen	Baltimore,	1936
Arthur W. Booth	Elmira, N. Y.,	1937
Rock Sleyster	Wauwatosa, Wis.,	1937

JUDICIAL COUNCIL

F. W. Cregor	Indianapolis,	1933
James B. Herrick	Chicago,	1934
G. E. Follansbee, Chairman	Cleveland,	1935
Walter F. Donaldson	Pittsburgh,	1936
Edwin P. Sloan	*Bloomington, Ill.,*	1937
Olin West, Secretary, ex officio	Chicago	

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

James S. McLester	Birmingham, Ala.,	1933
Emmett P. North	St. Louis,	1934
Reginald Fitz	Boston,	1935
M. W. Ireland	*Washington, D. C.,*	1936
Charles E. Humiston	Chicago,	1937
Frederic A. Washburn	Boston,	1938
R. L. Wilbur, Chairman	Wash'n, D. C.,	1939
W. D. Cutter, Secretary	Chicago	

COUNCIL ON SCIENTIFIC ASSEMBLY

Roger S. Morris	Cincinnati,	1933
Irvin Abell	Louisville, Ky.,	1934
Frank Smithies	Chicago,	1935
J. E. Lane, Chairman	New Haven, Conn.,	1936
Frank H. Lahey	Boston,	1937

AND EX OFFICIO

The President-Elect, the Editor and the Secretary of the Association.

COMMITTEE ON SCIENTIFIC EXHIBIT

D. Chester Brown, Chairman	Danbury, Conn.
Arthur W. Booth	Elmira, N. Y.
Allen H. Bunce	Atlanta, Ga.
Thomas G. Hull, Director	Chicago

ADVISORY COMMITTEE

George Blumer	New Haven, Conn.
Paul J. Hanzlik	San Francisco
Ludvig Hektoen	Chicago
Urban Maes	New Orleans
Hans Zinsser	Boston
Ralph H. Major	Kansas City, Kan.
John E. Lane, ex officio	New Haven, Conn.

COUNCIL ON PHARMACY AND CHEMISTRY

(Standing Committee of Board of Trustees)

R. A. Hatcher	New York,	1933
E. E. Irons	Chicago,	1933
H. N. Cole	Cleveland,	1933
Stanhope Bayne-Jones	Washington, D. C.,	1934
C. W. Edmunds	Ann Arbor, Mich.,	1934
Eugene F. Du Bois	New York,	1934
Morris Fishbein	Chicago,	1935
G. W. McCoy	Washington, D. C.,	1935
E. M. Bailey	New Haven, Conn.,	1935
George H. Simmons	Chicago,	1935
L. G. Rowntree	Philadelphia,	1936
Torald Sollmann	Cleveland,	1936
Lafayette B. Mendel	New Haven, Conn.,	1936
Reid Hunt, Chairman	Boston,	1937
W. W. Palmer	New York,	1937
Alfred F. Hess	*New York,*	*1937*
Paul Nicholas Leech, Secretary	Chicago	

COMMITTEE ON FOODS

(Special Committee of Board of Trustees)

E. M. Bailey	New Haven, Conn.
Julius H. Hess	Chicago
L. B. Mendel	New Haven, Conn.
G. F. Powers	New Haven, Conn.
Morris Fishbein, Chairman	Chicago
Philip C. Jeans	Iowa City
R. M. Wilder	Rochester, Minn.
Raymond Hertwig, Secretary	Chicago

COUNCIL ON PHYSICAL THERAPY

(Standing Committee of Board of Trustees)

Ralph Pemberton	Philadelphia
Harry E. Mock, Chairman	Chicago
W. E. Garrey	Nashville, Tenn.
A. U. Desjardins	Rochester, Minn.
George Miller MacKee	New York
H. B. Williams	New York
W. W. Coblentz	Washington, D. C.
John S. Coulter	Chicago
Robert B. Osgood	Boston
Frederick J. Gaenslen	Milwaukee
Howard T. Karsner	Cleveland
Olin West, ex officio	Chicago
Morris Fishbein, ex officio	Chicago
Howard A. Carter, Secretary	Chicago

BUREAU OF LEGAL MEDICINE AND LEGISLATION

W. C. Woodward, Director - - - Chicago

BUREAU OF HEALTH AND PUBLIC INSTRUCTION

W. W. Bauer, Director - - - - - Chicago

BUREAU OF INVESTIGATION

Arthur J. Cramp, Director - - - - Chicago

BUREAU OF MEDICAL ECONOMICS

R. G. Leland, Director - - - - - Chicago

CHEMICAL LABORATORY

Paul Nicholas Leech, Director - - - Chicago

LIBRARY

Marjorie Hutchins, Librarian - - - Chicago

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Reginald Fitz, Boston; Vice Chairman, I. I. Lemann, New Orleans; Secretary, W. J. Kerr, University of California Hospital, San Francisco.

SURGERY, GENERAL AND ABDOMINAL—Chairman, Fred W. *Rankin, Rochester, Minn.; Vice Chairman,* Lloyd Noland, Birmingham, Ala.; Secretary, Howard M. Clute, 605 Commonwealth Avenue, Boston.

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY—Chairman, Barton Cooke Hirst, Philadelphia; Vice Chairman, Willard R. Cooke, Galveston, Texas; Secretary, James R. McCord, 50 Armstrong Street, Atlanta, Ga.

OPHTHALMOLOGY—Chairman, Frederick H. Verhoeff, Boston; Vice Chairman, Charles A. Bahn, New Orleans; Secretary, Parker Heath, 1551 Woodward Avenue, Detroit.

LARYNGOLOGY, OTOLOGY AND RHINOLOGY—Chairman, Harris P. Mosher, Boston; Vice Chairman, J. L. Myers, Kansas City, Mo.; Secretary, John J. Shea, *1018* Madison Avenue, Memphis, Tenn.

PEDIATRICS—Chairman, Fred W. Schlutz, Chicago; Vice Chairman, M. G. Peterman, Milwaukee; Secretary, Alfred A. Walker, Highland Plaza Apartments, Birmingham, Ala.

PHARMACOLOGY AND THERAPEUTICS—Chairman, E. M. K. Geiling, Baltimore; Vice Chairman, John H. Musser, New Orleans; Secretary, C. H. Greene, *303 East 20th* Street, *New York.*

PATHOLOGY AND PHYSIOLOGY—Chairman, Clyde Brooks, New Orleans; Vice Chairman, William Carpenter MacCarty, Rochester, Minn.; Secretary, J. J. Moore, 55 East Washington Street, Chicago.

NERVOUS AND MENTAL DISEASES—Chairman, George B. Hassin, Chicago; Vice Chairman, Titus Harris, Galveston, Texas; Secretary, *Henry W. Woltman, Mayo Clinic, Rochester, Minn.*

DERMATOLOGY AND SYPHILOLOGY—Chairman, Francis Eugene Senear, Chicago; Vice Chairman, Howard T. [illegible] Secretary, Harry R. Foerster, 208 East Wis[illegible]

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH—Chairman, J. N. Baker, Montgomery, Ala.; Vice Chairman, W. H. Perkins, New Orleans; Secretary, Wilson G. Smillie, 55 Van *Dyke* Street, *Boston.*

UROLOGY—Chairman, N. G. Alcock, Iowa City; Vice Chairman, J. U. Reaves, Mobile, Ala.; Secretary, J. H. Morrissey, 40 East *61st* Street, New York.

ORTHOPEDIC SURGERY—Chairman, W. Barnett Owen, Louisville, Ky.; *Vice Chairman, J. S. Speed,* Memphis, Tenn.; Secretary, Fremont A. Chandler, 180 North Michigan Boulevard, Chicago.

GASTRO-ENTEROLOGY AND PROCTOLOGY—Chairman, Curtice Rosser, Dallas, Texas; Vice Chairman, A. F. R. Andresen, Brooklyn, N. Y.; Secretary, H. L. Bockus, 250 South 18th Street, Philadelphia.

RADIOLOGY—Chairman, George W. Grier, Pittsburgh, Pa.; Vice Chairman, W. Walter Wasson, Denver; Secretary, John T. Murphy, *421 Michigan Street, Toledo, Ohio.*

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER, 1932

Abstracts of important articles in the following journals have been made in the Current Literature Department of The Journal during the past six months. Any of the journals, except those starred, will be lent by The Journal to subscribers in continental United States and Canada and to Fellows of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1925. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

Acta Chirurgica Scandinavica. Stockholm.
Acta Dermato-Venereologica. Stockholm.

SUBJECT INDEX

This is an index to all the reading matter in The Journal. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ME," Medical Economics; "ab," abstract; the star (*) indicates an original article in The Journal.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2349.

  witnesses, medical; attending physician may base opinion on absent roentgenograms, when, 2058
  witnesses, medical; attending physician versus expert witness, 856
  witness, medical; complaints of examinee's, opinion based on, 682
  witnesses, medical; complaints of patients, opinion based on, 682, 2058, 2290
  witnesses, medical expert; see also Malpractice
  witnesses, medical expert; books used in cross-examination, 784
  witnesses, medical expert; competence, school of medicine as affecting, 250; 332
  witnesses, medical expert; evaluation of testimony, *856*
  witness, medical; complaints of examinee's, report to patient's counsel privileged, 250
  witnesses, medical expert; opinion based on absent roentgenograms; admissibility, 942, 2058
  witnesses, medical expert; opinion invading province of jury, 416, 1019
  witnesses, medical expert; qualifications determinable by trial court, 1806
  witnesses, medical expert; qualifications of sectarian practitioners, 250

Medicolegal Abstracts—Continued
EVIDENCE—Continued
  witnesses, medical expert; roentgenograms not in evidence, admissibility of opinion based on, 942, 2058
  witnesses, lay; opinion testimony; syphilis, presence of, 416
EYE: retina; detachment of attributed to strain, 2058
FRIGHT: white hair attributed to, 502
GESTATION: duration of, 502
HAIR: whitening of attributed to accident, 502
HEART: acute dilatation following over-exertion, 2212
HEMORRHAGES: cerebral; testamentary capacity in relation to, 1630
HERNIA: trauma as cause of, 2290
HOMEOPATHY: homeopathic physician as expert witness concerning surgical standards, 250
HOSPITALS, CHARITABLE: liability for: burns, hot-water bottle, 250
  liability for: employees, selection of, 2290
  liability for: equipment, injury from defect in, 2290
  liability for: nurses, negligence of, 856
  liability of; general principles underlying, 250
  liability to pay patients, 856, 1720
  liability to visitors, 1720
  status; criteria of charitable character, 65
HOSPITALS FOR PROFIT: liability for: escape of patient, 855
  liability for: interns, negligence, 682
  liability for: physicians, negligence of, 1454
HOSPITALS, IN GENERAL: clinical use of patients, 1454
  records; when public records, 1110
  superintendent; selection of lay superintendent as negligence, 2290
  vaginal examinations by medical students, 1454
INITIATIVE AND REFERENDUM: amendment by legislature (Calif.), 2212
INJURIES: permanency; what constitutes, 2058
ILLEGITIMACY: See Gestation, duration of
INSANITY, IN CIVIL RELATIONS: annulment of marriage for, 856
INSURANCE: accident; retina, detachment of, following strain, an "accident," 2058
  health; medical treatment by mail, 856
INTERNS: liability for negligence, 682
  performance of usual duties as practice of medicine, 682
JURORS: treatment by chiropractor as disqualifying, 1019
MALPRACTICE: abortions; civil liability of physician after criminal abortion, 65
  action in tort no bar to action on contract, when, 1019
  burns; hot water bottle, 250
  burns; "sweat box" or electric light baths, 1630
  childbirth; burns from dry heat treatment for convulsions, 1630
  childbirth; patient examined by medical students, 1454
  childbirth: placenta left in uterus, 1454
  childbirth; septicemia following, 1454
  convulsions; burns from dry heat treatment, 1630
  corporations; liability of incorporated clinic, 1380
  cure; warranty by physician; tort action no bar to action on contract, 1019
  cyst; facial paralysis following removal of, 1380
  damages; release of tort feasor who caused original injury, 2212
  deafness; attributed to use of eustachian catheter, 161
  dentists; hypodermic needle broken in gum, 332
  dentists; osteomyelitis attributed to extraction of tooth, 1538
  employers; liability of, 1454
  evidence; res ipsa loquitur, 332, 855, 2290
  evidence; witnesses, medical expert; competence, school of medicine as affecting, 250, 332
  evidence; witnesses, medical expert; homeopath as, 250
  evidence; witnesses, medical expert; necessity for, 161, 1454
  evidence; witnesses, medical expert; qualifications, 1290
  experiments with secret devices; liability, 1290
  foreign bodies; needles, 332, 1200
  foreign bodies; needles; implied consent to operation for removal, 1200
  fracture of femur; by osteopath, 332
  hypodermic needle; point left in gum, 332
  interns; duty to hospital patient, 682
  limitation of actions; fraud suspends statute, 2140
  negligence; proof of necessary, 161
  nurses; duty to hospital patient, 682
  nurses; liability of physician for neglect, 250
  nurses; relative liability of nurse and physician, 1630
  nurses, special; liability for defective hospital equipment, 2290
  operations; consent; husband's consent unnecessary, when, 1200
MALPRACTICE—Continued
  operations; *consent*; implied, when, 161, 1200
  osteomyelitis attributed to extraction of tooth, 1538
  osteomyelitis; treatment by "radio method," 1290
  osteopath; femur fractured by, 332
  osteopath; skill; standard by which judged, 1290
  paralysis, facial; following removal of branchial cyst, 1380
  privacy; invasion of right of, 1454
  "radio method;" osteomyelitis treated by, 1290
  res ipsa loquitur, 332, 855
  roentgenograms; failure to make before extracting infected tooth, 1538
  skill; standards; by which sectarian healers judged, 1290
  teeth; osteomyelitis attributed to extraction, 1538
  tort feasors; judgment against as affecting physician's liability, 1454
  tort feasors; release of as affecting physician's liability, 2212
  vaginal examination: septicemia attributed to, 1454
MARRIAGE: annulment; insanity as grounds for, 856
MEDICAL PRACTICE ACTS: See also Basic Science Acts
  chiropractic; as practice of medicine, 1019, 1110
  chiropractic; "Dr.," use of title, 2212
  chiropractic; initiative statute (Calif.); relation to medical practice act, 2212
  Christian science; as practice of medicine, 1806
  corporations; practice of dentistry by, 1976, 1977
  evidence: opinion of defendant invading province of jury, 1019
  evidence; results of treatment, 1019
  examining boards; de facto boards, 1720
  exceptions; religious freedom, 1806
  initiative chiropractic statute (Calif.); effect on medical practice act, 2212
  interns; performance of usual duties when unlicensed, 682
  licenses, revocation; aiding corporation to practice, 1976, 1977
  licenses, revocation; aiding unlicensed practitioner, 249, 1538
  licenses, revocation; board's action not conclusive on court, 1976
  licenses, revocation; causes for determinable by legislature only, 1720
  licenses, revocation; causes for stated in general terms, validity, 65
  licenses, revocation; complaint, sufficiency of, 249, 1538
  licenses, revocation; conviction for crime, 1720
  licenses, revocation; de facto board, 1720
  licenses, revocation; employing unlicensed person, 1976
  licenses, revocation; "gross carelessness and manifest incapacity," 65
  licenses, revocation; gross unprofessional misconduct, 1977
  licenses, revocation; gross violation of professional duty, 1976
  licenses, revocation; mandamus as appeal procedure, 588
  licenses, revocation; notice to defendant, sufficiency of, 1720
  licenses, revocation; proceedings must conform to statutory requirement, 588
  licenses, revocation; qualifications of members of medical board, 1720, 1977
  licenses, revocation; right to revoke includes right to suspend, 1976
  licenses, revocation; unprofessional and dishonest conduct, 1720, 1976
  licenses, suspension; right to revoke includes right to suspend, 1976
  mechanotherapy; as practice of medicine, 784
  nuisances; violations of medical practice acts as, 1886
  physical therapy; as practice of medicine, 784
  professional titles; restrictions as to use, 2212
  prosecutions; injunctions; constitutionality of statute, 1886
  prosecutions; injunctions: future violations need *not* be alleged, 1886
  prosecutions; injunctions; trial by jury, right of not violated, 1886
  prosecutions; quo warranto, enforcement by, 784
  religious freedom in relation to, 1806
  repeal by implication, 2212
  titles, professional; use of by unlicensed person, 332
  violations of; injunctions to prevent, 1886
NUISANCES: violations of medical practice acts as, 1886
NURSES: negligence of; charitable hospital's liability for, 856
  negligence of; relative liability of nurse and physician, 682, 1630
  special nurses; defective hospital equipment, liability for injury from, 2290
  special nurses; negligence of, physicians liability for, 250
OSTEOMYELITIS: "radio method" used in treatment of, 1290
  tooth extraction as cause of, 1538
OSTEOPATHS: see Malpractice
PHARMACISTS: degree of care required, 588
  drugs; liability for quality of, 588
PHARMACY PRACTICE ACTS: drugs; proprietary medicines defined, 588
PHYSICAL EXAMINATIONS: roentgenograms; statute authorizing court to order, validity, 502
PNEUMONIA: septic; compensability under workmen's compensation acts, 856
POISONING: *lead*; compensability *under* workmen's compensation acts, 588
PREGNANCY: abdominal, trauma and therapeutic abortion, 942
  duration of, 502
PRIVILEGED COMMUNICATIONS: disclosures; by consultants, 416
  disclosures; by examining physician, in personal injury cases, 250
  disclosures; by partners, 416
  disclosure to third party at instance of physician privileged, 416
  evasion of statute, 416
  observations not connected with treatment, 1886
  waiver; suit for personal injury does not *constitute* waiver, 250
QUARANTINE: venereal *diseases*; health officer may exercise discretion, 65
  venereal diseases; not punishment for a felony or misdemeanor, 65
  venereal diseases; quarantine by health officer not violative of due process, 65
RETINA: detachment of attributed to strain, 2058
ROCKY MOUNTAIN SPOTTED FEVER: compensability under workmen's compensation acts, 502
ROENTGENOGRAMS: see also Malpractice; Evidence
  court may require plaintiff to be roentgenographed, 502
STRAIN (OVER-EXERTION): detachment of retina attributed to, 2058
  heart; acute dilatation attributed to, 2212
SYPHILIS: lay testimony as to absence of, 416
TRAUMA: abortion, therapeutic, as necessitated by, 942
  appendicitis attributed to, 2290
  hernia attributed to, 2290
  pneumonia, septic, in relation to, 856
  white hair attributed to, 502
TULARAEMIA: compensability under workmen's compensation acts, 1806
VENEREAL DISEASE: see Quarantine
WILLS: testamentary capacity; cerebral hemorrhage in relation to, 1630
  testamentary capacity; criteria of, 1630
  testamentary capacity; disease in relation to, 1630
  testamentary capacity; epilepsy in relation to, 784
  testamentary capacity; evidence; lay testimony, 784
  testamentary capacity; evidence; limits of *testimony concerning*, 416
  testamentary capacity; evidence; opinion of *attending physician*, 416
  testamentary capacity; forgetfulness in relation to, 1630

SOME PRESSING PROBLEMS IN ALLERGY

CHAIRMAN'S ADDRESS

J. H. BLACK, M.D.
DALLAS, TEXAS

In spite of the fact that the treatment of allergic conditions is fairly satisfactory, the fact remains that treatment is largely empiric. Advantage is taken of the fact that allergic persons frequently show skin reactions to their respective allergens to determine the specific allergenic substances, but there are many irregularities found in skin reactivity and the reasons for them are imperfectly understood. Treatment with the substance to which the patient is sensitive frequently produces good results, but there is still much room for argument as to the mechanism underlying the response to treatment. Some of the problems found in an attempt to explain these conditions are due to deficiencies in the knowledge of immunology in general, but some of them may be solved by careful, concerted study by the clinical investigator and the laboratory worker. In this field where animal experimentation may fail to reproduce human reactions, accurate observation of carefully controlled patients may provide the material for the solution of some vexing problems. A few of these problems which deserve attention will be mentioned.

BASIS FOR HEREDITARY INFLUENCE

One of the most definite findings in allergy is the hereditary transmission of "something." Since this frequently is not the transmission of the identical sensitiveness of parent to child as to either allergenic substance or location of the site of reaction, the usual statement made is that the inheritance is of a "tendency." This is a term used to represent an intangible thing and, of course, answers no questions. Would it not be possible to assume that this transmitted "tendency" has its basis in the transmission of some anatomic abnormality which may be just as definite as polydactylism and just as definitely conforming to the laws of inheritance? Would it not be possible to believe that persons are allergic because of an abnormal type of response that has its basis in abnormal function which, in turn, results from an anatomic variation? There is, of course, no present proof available for such an assumption, but to my mind it produces no greater strain on the imagination than to speak of a "tendency" and has the distinct advantage of reminding one that the search for a basis—anatomic, physiologic or chemical—should be kept in mind and offers a concrete goal toward which to work.

There has been no lack of attempt to explain allergic phenomena on an immunologic basis, but there is reason to believe that the treatment of a specific type of reaction, e. g., asthma, with the specific allergen is, after all, symptomatic treatment. The facts that multiple sensitivity is the rule, that persons become sensitive to one thing after another and that clinical sensitiveness is frequently the result of exposure to some particular allergen and, consequently, may be considered as accidental, all tend to call attention to the fact that the allergic person has a fundamental abnormality which may manifest itself in various ways depending on different conditions. That this fundamental abnormality is the same in all allergic persons and the different manifestations are more or less accidents is a possibility which deserves consideration. It may seem a rash prophecy, but it is not entirely impossible that at some time this fundamental condition may be determined and the treatment of all allergic persons then become the same.

RELATIONSHIP OF ENDOCRINE ORGANS AND INVOLUNTARY NERVOUS SYSTEM

Various observers have suggested the possible influence of one or another of the endocrine organs. Objection can be raised to these assumptions, and lack of substantial evidence can be shown in every instance. The involuntary nervous system also has been incriminated, but only a mass of conflicting observations and opinions has resulted. However, the fact remains that many of the phenomena associated with allergy may be duplicated by activity of one or another part of the involuntary nervous mechanism. There is certainly much evidence to support the belief that allergic reactions are mediated by the involuntary nervous system. Whether the relationship is even more fundamental than this deserves consideration. The low blood sugar, the low blood pressure and the slow pulse rate so frequently seen in allergic persons cannot be mere accidental happenings. Just what their significance may be needs to be investigated. More and more the conviction is growing that eosinophilia is a manifestation of autonomic nervous action. Its common association with allergic reactions surely has more than diagnostic significance.

RELATION OF REAGIN TO CLINICAL HYPERSENSITIVENESS

Emphasis has been placed on the immunologic aspects of allergy, and a great deal of discussion has been

---

Read before the Section on Pathology and Physiology at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932.

carried on regarding the place of allergy in the classification of the various types of hypersensitiveness. The finding of reagin in the blood of allergic persons has led to the assumption that this antibody is responsible for the clinical manifestations of allergy. Definite differences, on the other hand, from the anaphylactic antibody have led to a refusal of some workers to designate allergy as a type of anaphylactic reaction. Evidence which has resulted from clinical observation tends to question some assumptions regarding the reagins. If this antibody is responsible for the clinical manifestations of allergy, how can one account for reagins for substances to which the patient shows no clinical sensitiveness or absence of reagin in the presence of clinical sensitiveness? Or how may the persistence of reagin long after the disappearance of all evidence of clinical sensitiveness be explained? It may be assumed that differences in reactivity of the "shock organ" may explain quantitative differences between amount of reagin and intensity of clinical manifestation, but this will not explain clinical sensitiveness of high degree with a total absence of reagin. It is true that in a great number of allergic persons reagin may be demonstrated, but it is equally true that in a not inconsiderable number reagin cannot be found. It may not be amiss to say that this subject deserves further study.

Dependent on the conception of the rôle of reagin is the belief as to the mechanism of specific treatment. If the reagin is the antibody mediating clinical sensitiveness, treatment is not desensitization, since it has been shown that the reagin is not diminished but may actually be increased as the result of treatment. If the reagin is not assigned this rôle, the question of what is being done in treatment is still open for investigation.

REACTIVITY OF THE SHOCK ORGAN

Differences in location of allergic manifestations have led to the assumption that there is at least a quantitative difference in the allergic state of the shock organs. Two persons exposed in the same manner to equal amounts of ragweed pollen may react, one with hay fever and the other with asthma. It has been commonly observed, however, that in constitutional reactions resulting from over-dosage in pollen treatment, the patient who has had an uncomplicated hay fever may react with hay fever, asthma and urticaria. In other words, a shock organ which has not shown clinical evidence of sensitiveness may, by this method of introduction of allergen into the body, respond with a violent reaction. Is this due to the unusual method of entrance of the allergen which causes qualitative differences from the allergen as usually introduced? Or it is due to a low grade sensitiveness of certain shock organs which will react under the stimulus of a larger dose?

Not only must one speculate as to why the skin of some allergic persons reacts to a given allergen while the respiratory mucosa does not, but one is confronted with the fact that in some persons recurring reactions tend to appear at the same site or sites while other skin areas remain unaffected. This would lead one to suspect the possibility of sensitization of one shock organ alone, and, indeed, of only parts of this organ. Some confirmation of this opinion is found in the fact that in some persons showing localized allergic reactions of the skin, positive reactions to the allergen may be obtained in these areas and not in other parts of the skin. The possibility of sensitizing limited areas has been seen recently in a patient, sensitive to wheat by ingestion, who had a localized eczema on the arms. Fragments of bread were strapped on his forearm and neck—two locations showing no eczema. No reaction occurred. However, two weeks later when the patient ate wheat, patches of eczema appeared exactly defining the location of the patch tests. Apparently sensitization of the sites had occurred, though no reaction was apparent within two weeks of the use of the patch test.

LOCAL IMMUNITY OR SENSITIZATION?

It is not a rare experience to see a sharp local reaction to an injection of pollen if the injections have been made previously in one arm and a change is made to the other arm which had received no injections prior to that time. The usual explanation given is that repeated injections into the same site bring about a certain amount of local immunity—or tolerance—so that an increase in dosage does not cause increased local reaction. On the other hand, not infrequently one sees a patient in whom injections have been made in each arm alternately and in whom an injection into one arm brings about an edematous area at the site of a previous injection in the other arm. The usual explanation given is that the injections have brought about a local sensitization which may cause a reaction when circulating allergen, injected into the other arm, reaches the sensitized area. Is it possible, then, that injections of pollen can produce both immunity—or tolerance—and sensitiveness at the site of the injection? Or do injections of pollen sometimes sensitize locally and sometimes immunize? Information on this subject would be valuable.

RATE OF ABSORPTION OF ALLERGEN

Cohen and his associates have offered evidence to show that the reaction of passively sensitized areas occurs later in allergic than in nonallergic persons when the allergen is introduced through the nasal mucosa or parenterally. And, conversely, every one doing clinical work with allergic persons has had the opportunity of seeing a constitutional reaction appear with startling rapidity after an injection of pollen which could be shown not to have entered a blood vessel. An explanation of these contradictory findings may have a definite bearing on the mechanism of the allergic reaction.

SENSITIZATION TO NONANTIGENIC SUBSTANCES

Most immunologists have refused to classify as allergens nonantigenic substances to which hypersensitiveness may be shown, on the ground that the substance is nonantigenic, there is no demonstrable inheritance and no reagins are found. But the fact remains that reactions from these substances may be clinically indistinguishable from true allergic reactions, and these persons are, after all, specifically sensitive. If one patient is specifically sensitive to cow hair and, on exposure, develops asthma while another person, specifically sensitive to cow hair, on contact develops a dermatitis, even though it may be shown that the chemical fraction causing asthma is not the same as that causing dermatitis, there still remains the fact that both persons are specifically sensitive. After all, may not the fundamental mechanism be the same? A considerable experience with "contact dermatitis" demonstrates that the substances causing the skin reaction are more commonly not irritants to the normal skin, that repeated or prolonged exposures frequently are not necessary to produce reactions and that the persons showing the lesions are specifically sensitized. Whether the present classification will stand under further investigation remains to be seen. Certainly when one remembers Sulzberger's experiment in which he was able to produce lesions in certain European guinea-pigs but could not similarly sensitize American guinea-pigs, the conclusion is forced on one that there may be conditions affecting the various manifestations of hypersensitiveness which so far have not been taken into account.

CONCLUSION

These points have been raised, not with the intention of disparaging the work which has been done, but to call attention again to the fact that there is a great amount to be done if work in allergy is to be placed on a scientific basis, and to remind the clinician as well as the laboratory worker that careful painstaking observation may assist in the solution of some of these perplexing problems.

THOUGHTS ON MEDICAL EDUCATION IN THE UNITED STATES

W. S. THAYER, M.D.
BALTIMORE

Nine and twenty years ago this very month it was my privilege to preside at the meetings of this section in this delightful city. The picture of that week is a bright spot in my memory. Two occasions stand out sharply against a background of fruitful discussion and unbounded hospitality. The first was the discussion on yellow fever at the opening session of the Section on Practice of Medicine. The second was the address of the President of the Association.

It had seemed to us important that the discoveries of the Yellow Fever Commission in Cuba should be impressed on the American medical profession. One of the three referees chosen for this discussion was a distinguished teacher, no longer young in years, who had made us somewhat uneasy by requesting that he be allowed more than his allotted time. Although he was a brilliant and scholarly man with a distinguished career and a wide experience with yellow fever, we had feared that, at his age, he might not be willing to accept demonstrations which seemed to us convincing, and when, at the last minute, one of his two colleagues failed us, it was an anxious m[illegible]t. From the platform I wrote a line to Dr. W[illegible]o was in the audience, begging him to come [illegible]cue in the discussion. James Carroll was [illegible] referee. Then his co-referee, a young man o[illegible]ature years—for there was no younger man than he in the audience—arose. Fluently, within the time allowed him, he spoke of the relation of fomites to yellow fever infection, and pointed out the significance of the new work with a simplicity and a lucidity so convincing as to preclude all discussion. It was a masterly, and withal a rather dramatic performance, and no one who listened to Chaillé at that notable session is likely to forget it.

The other occasion was the address of the President, which was impressive, not only for the substance of the spoken words. The words were wise but the bearing, the physique, the face, the voice, the manner of the speaker made a lasting impression on more than one of the audience and deepened the feeling that was already ours, that this was no ordinary man. I need not say that the President of the Association was Frank Billings. His subject was "Medical Education in the United States."[1] In this address Billings set forth the broad ideals of the university school of medicine. Clearly and convincingly he pointed out that medicine, an applied science, should be taught in scientific fashion; that the instruction in such branches as anatomy, physiology, pharmacology and chemistry should be carried on in the laboratory by men who give their lives to teaching and investigation; that only students, salaried professors, could give such instruction; that furthermore, the study of diagnosis and treatment of disease should be carried out in special hospitals controlled by universities under the direction of

> professors of medicine, of surgery, and of obstetrics, with competent assistants, of the same type as the teacher of the fundamental sciences. . . . It is time, therefore, that the clinical teacher should have the knowledge necessary to carry on experimental investigation, with hospital facilities for the work that the profession may become purged of the shame of its helplessness in curing so many of the common diseases of mankind. In addition to the clinical teachers, who will devote all their time to teaching and research work in the special hospitals, there will be quite as much need for the clinical teacher, who is in private practice, in the general hospitals. . . . His rich and varied experience in hospital and private practice will enable him to round out the student's college education. . . . He will teach the student the art of medicine. . . . The present status of medical science requires and demands a university medical college course. By university medical college is meant a medical school which is directly connected with and a part of a university; the university fixing the requirements and controlling the admission of students to the medical department. The method of teaching both the fundamental and the clinical branches is on the principles outlined above. To properly prepare for such a course the student should have, as a *minimum* preparation, at least two years of study in a good college or university. The requirements to enter a good college or university would insure a sufficient knowledge of the ordinary school branches and also Latin or Greek. During the two years' course in college his time would be well spent in the study of English, French, German, mathematics, history, philosophy, physics, chemistry, general and organic, and qualitative analysis, comparative anatomy and general biology. The amount of time to be devoted to each of these subjects would be the same as that of students of general science, as arranged in all college curricula, with the exception of a much more thorough course in chemistry, biology, physics and comparative anatomy.
>
> So prepared, the medical matriculate would be able to grasp all the intricacies of the subjects of the fundamental branches of medicine. With the addition of the full medical college course as outlined above, his education would be equal in culture to that of the graduate in arts and philosophy. At the same time, it would be practical and especially fit him for his work as a scientific investigator or practitioner, or for both.
>
> With the medical profession so educated a physician would be, in truth, a member of a learned profession. From an educational point of view he would rank as an equal with the scholar in philosophy, law and theology. . . . As the direct agent by which the American Medical Association may exert its influence in the elevation and control of medical education, the Committee on Medical Colleges and Medical Education should be made permanent and should be given adequate power and sufficient annual appropriation to make its work effective.

These wise words were followed by a movement which has resulted in a great and general improvement of medical education in the United States, a movement

---

The Frank Billings Lecture, read before the Section on Practice of Medicine at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 11, 1932.

[1] Billings, F.: Medical Education in the United States, J. A. M. A. **40**: 1271 (May 9) 1903.

in which this Association has played a highly honorable part. Largely as the result of this address and of the recommendations of the Committee on Medical Colleges, presided over by Arthur D. Bevan, this committee was succeeded in the following year by the Council on Medical Education and Hospitals. It is hardly necessary to mention the active and courageous campaign carried on by this Council under Bevan's leadership. Its surprising revelations are still fresh in our memory, as is the remarkable report of Abraham Flexner to the Carnegie Foundation.[2]

Already, it is true, in better schools, teaching in the preclinical branches was fairly well endowed, and, at the Johns Hopkins University, several clinical departments had been established on what might properly be called a university plane.

In the last three decades much that Billings set forth as desirable has been realized. Many inferior proprietary schools have disappeared. The great majority of the seventy-six schools of medicine recognized by this Association are connected with universities. The teaching of anatomy, physiology, chemistry and pharmacology in these institutions is almost entirely in the control of students who give their whole time to instruction and research, who are, in a true sense, university professors. In a considerable number of schools clinical departments have, in like manner, been placed on what is essentially a university basis, the director receiving a salary sufficient to free him from many of the anxieties of life and to relieve him, more and more, from the necessity of practice for the support of himself and his family. Relatively adequate salaries have made it possible for younger men to devote valuable years of their life to the study of special problems, or, as assistants in scientific or clinical departments, to acquire that experience which may qualify them for consulting practice, for clinical teaching, or for the direction of others in scientific research.

Materially, in buildings and equipment, our schools of medicine are second to none. Through the generosity of individuals and foundations for the furtherance of good works, laboratories and institutes have been established in and outside of the university, the scientific contributions of which are recognized throughout the world. The amount of scientific work done not only in institutes for research, but also in our schools of medicine, is really considerable. The volume of this work becomes more impressive when one considers the serious monthly medical publications of thirty years ago and today. In 1903, the *American Journal of Medical Sciences*, the *Journal of Experimental Medicine*, the *Journal of Medical Research*, the *American Journal of Physiology*, the *American Journal of Anatomy*, which had just begun its career, and a few other special magazines were the only serious American agencies for the publication *in extenso* of original investigations. Think of the amount of really good original work which appears today in the special publications of this Association alone.

The day has already come when students from the old world are turning to our universities and our laboratories as for years we have turned to theirs—a happy omen.

At the same time, an earnest effort has been made to raise the standards for admission to our schools of medicine. With the advances in medical knowledge and the increased application of the natural sciences, such as chemistry and physics, to the problems of physiology, normal and pathologic, the student of medicine must have not only a wider general education, but a more thorough understanding of the natural sciences. Some of our universities demand a degree of Bachelor of Arts or Science for admission to the school of medicine. Minimal requirements for admission to the approved schools of medicine have, for many years, been insisted on by the Council on Medical Education, requirements which demand a four years high school course and at least two years of premedical study in a college or university, in which special stress is laid on chemistry, physics, biology and English; a reading knowledge of one foreign language is strongly urged. The necessity of adequate clinical experience is more generally recognized. Such experience in the wards of the hospital during the undergraduate period, offered in but few schools thirty years ago, is now general, and eleven schools demand a fifth or clinical year. City and state hospitals are recognizing that their efficiency is increased and their reputation enhanced by opening their doors to university teachers and students, and university units for teaching and investigation in public institutions are no longer uncommon.

Sixteen states demand a year's experience as clinical intern in more or less carefully designated hospitals before granting an application for a licence to practise. More and more, state examiners are emphasizing practical tests of clinical ability; this is notably true of the admirable work of the National Examining Board.

It is really interesting to consider how much of Billings's program, if one may so call it, has already been realized:

The elimination of proprietary schools and the change in character of those which remain.

The almost universal relegation of preclinical instruction to salaried professors who give their entire time to teaching and investigation.

The widespread assumption of medical teaching by universities.

The building of university hospitals.

The affiliation of private hospitals with universities.

The organization of such hospitals on what might be called a university basis, in the sense of the centralization of responsibility and the giving of adequate salaries to the directors of clinical departments.

The establishment of university units in general hospitals.

The multiplication of endowed professorships, laboratories and institutes of research.

The adoption of higher standards of admission to schools of medicine.

The improvement of the character of state examinations for a licence to practise medicine, and the more general reciprocity between state examining boards.

The work of the National Examining Board.

Brilliant contributions to science and therapy have come from the laboratories and clinics of the medical departments of universities.

One need but mention:

The information we have gained on problems of metabolism in general.

The addition to our knowledge of food values and vitamins in relation, for instance, to rickets, pellagra, beriberi, xerophthalmia and the anemias.

The numerous contributions to our knowledge of the internal secretions of pituitary, thyroid, parathyroid, pancreas, adrenals, ovaries.

The brilliant therapeutic effects of insulin in diabetes, of liver extract and ventriculin in pernicious anemia.

---

[2] Flexner, Abraham: Medical Education in the United States and Canada: A Report to the Carnegie Foundation for the Advancement of Teaching, New York, 1910.

The isolation of epinephrine, insulin, thyroxine.

Our steady progress in the comprehension of infectious processes in general.

These are but a few of the discoveries that are flowing from university schools of medicine.

There are, of course, critics of the modern tendencies in medical instruction—on the one hand, those who question the fundamental soundness of the methods themselves, and on the other hand, those who criticize the wisdom and efficacy with which we have administered or carried out our program.

Among the former group there have always been those who feel that we are attempting too much, who "point with alarm" to the diminishing number of country practitioners, and assert that it is difficult to conceive that a man with so good a general education as the medical graduate of today would willingly live the life which was led in the past by him who served the country community in the days of our fathers. These men earnestly ask whether we should not have simpler schools with a shorter course and less severe requirements to provide doctors of a simpler class for such communities.

And then there are the others who feel that with the increased demands for admission to schools of medicine too many men with qualities which might easily admit of their becoming useful practitioners are definitely shut out from a medical career because of their lack of means.

While I respect the sincerity with which both of these objections are often made, I cannot feel that they need serious consideration. In the first place, in many regions improved means of communication have made good medical attention available as never before. In distant rural districts the remedy is surely not to be sought by providing inferior men.

These are problems which must be considered and met by community, county and state. The medical profession will be found ready, as it always has been, to do its share. The occasional local controversies between physicians, individual and in bodies, private charitable foundations and state agencies are deplorable for the moment, but usually settle themselves in the end for the public good, for the very simple reason that, at heart, all are working toward the same end.

The second fundamental objection is one which always excites one's sympathy. Who can tell what boy, had he had every advantage, might have accomplished great things? All that we can do is to support the best possible system of schools, to offer the best opportunities we can. Nothing which we can do can prevent boys improperly educated from desiring to study medicine when it is too late. Nothing can prevent the occasional heartburnings. It is clear today that preparation for medicine demands a more thorough and careful education than has been given in the past. This is really not a matter for dispute. That this is not understood by the public at large is sad, but to a certain extent inevitable. In our public schools proper opportunities should be open to those able to avail themselves of them.

This great reorganization, for such it really is, of our methods of medical instruction, has, of itself, naturally given rise to new problems, a few of principle, many of detail.

Some of these relate to the teaching of the preclinical subjects. In the old days the instruction in anatomy and physiology, in the hands of men who were active practitioners, was very largely of an applied or practical character, the instructor having in mind, mainly, the relations between the established truths or accepted hypotheses which he was demonstrating, and the practice of surgery or medicine. Today the professor of physiology or of anatomy is generally a student and investigator working or directing work on scientific problems. Not infrequently such a man does not even hold a medical degree.

The first two years of the instruction in the modern medical school is given largely to anatomy, physiology, chemistry and perhaps pharmacology. When the student begins his studies of diagnosis, medical and surgical, his ideas of topographic and applied anatomy are vague. When, in the laboratory, he studied the tendons of the wrist, he had little thought of the application of this knowledge to surgical practice; when he begins, clinically, to examine the blood, not only is the procedure new but the histology itself comes to him almost as a new subject. When in connection with the study of pathologic changes of function, the student begins to consider physiologic problems in the human being, the relationship of that which he has observed in the laboratory on animals a year previously is by no means always clear.

The criticism is common that teaching of applied anatomy and physiology is neglected in the preclinical departments, that the professors of anatomy and physiology should always be surgeons or physicians, and that, in a medical school, instruction in anatomy and physiology should be carried on from the outset with an eye to their relation to medical and surgical problems.

There is truth in the assertion that the division between the abstract scientific and the applied clinical teaching is too sharp in most of our schools. I hope that one day this may be remedied. It seems to me, however, that the remedy lies not in changing the character of our departments of anatomy and physiology but in better cooperation. The teaching of topographic and applied anatomy and of applied physiology, such, for instance, as the demonstration of the percussion of the outlines of organs in the living human being, of the methods of appreciating the respiratory sounds or those produced in the cardiovascular apparatus and their physical explanation, are not, and should no longer be regarded as the duty of the anatomic or physiologic department. They should be taught by the clinical departments in closer cooperation with instruction in the preclinical branches than they now are. The day must come when, in well-ordered schools, study of the anatomy of the heart and lungs may be accompanied by the demonstration to the student of methods of determining these things clinically; when, for instance, in association with the consideration of the physiology of the respiration, the physics of the circulation and the character of the heart sounds, the student may make use of the ordinary clinical procedures by which we explore these functions. There are opportunities here for better cooperation.

I am not, however, in sympathy with those who would turn back to the old methods of teaching anatomy and physiology as purely applied sciences. One of our main objects should be to impress on the student that the clinician must reason for himself in a scientific fashion. The instruction in the preclinical branches in the modern university school should be carried on in such fashion as to exemplify Lowell's wise expression:

"self-education under guidance." President Ames[3] has well said:

> The primary duty of the university to a student is to provide such instructors that he is made to realize that the responsibility for progress is his own, no one else's. He must receive a certain amount of fundamental instruction; he must be given the technique of his field of study, he must be allowed to secure his information by himself, and largely in his own way; he must learn to look upon his field as one which has no limits and in which he must walk alone; . . .

These lessons should be inculcated from the very beginning of the student's medical instruction. Mall was one of the greatest teachers that I have known; but in his lifetime a common criticism of Mall was that he did not teach. He did teach anatomy as a science. He taught his students to stand on their own feet and think with their own heads. At the same time his laboratory and his material were always wholly at the service of the medical and surgical departments on which, properly, it seems to me, lies the duty of the teaching of applied anatomy and physiology.

I am not inclined to feel that it is in any sense necessary for a professor of anatomy or physiology to be the holder of a degree of Doctor of Medicine, although I believe it to be wiser and better that he should. The intelligent man who has been through a regular medical course certainly loses nothing by it, and gains a better appreciation of the problems which his students are to confront later in life.

I am therefore not in sympathy with those who criticize fundamentally the teaching of anatomy and physiology by men who are not Doctors of Medicine. While, other things being equal, a medical degree is desirable, it is not the degree that is important, it is the man. That the professor should be an unselfish, scholarly investigator with a human interest in his students and the capacity of stimulating them in their work—that is the essential point.

There has been a good deal of criticism of the idea of the university school of medicine based on the assumption that the teaching of the clinical branches may be too exclusively delegated to men who are rather investigators than clinicians, and that, in university schools, there has been a tendency to appoint to clinical professorships young men of scientific enthusiasm who have not had the experience necessary to give them a sufficient competence in their clinical methods; that these men, in some instances, have been so far overwhelmed by their administrative duties that, with a relatively small clinic, and deprived of the constant association with their colleagues which comes to the active consultant, they have failed to acquire the clinical skill and authority which is desirable. It has been urged that, in some university schools and hospitals, the opportunities in the way of beds and ward service for those clinical associates who should be called on in the teaching, opportunities which are necessary for the construction of an adequate teaching staff, have been deficient.

There has been, here and there, some justification for such criticism. It has not always been recognized, as it should be, that a well balanced staff, which should include a group of the best clinicians in the community, is quite necessary for the university school of medicine.

There have been institutions which have started with clinical advantages so limited as to provide only for the kernel of the university staff. This, as I have pointed out elsewhere,[4] has resulted in putting on younger and less trained members of the university staff, clinical duties which they were not yet qualified to fill, duties which have, at times, placed on them so great a burden as to interfere seriously with the opportunities to round out their own clinical experience in an orderly fashion and without undue strain.

Again, sometimes, professors appointed too early to positions of heavy administrative responsibility have developed into administrators rather than physicians, teachers or investigators, and a few classes of students have suffered from lack of adequate clinical instruction.

But only Pallas Athene sprang perfect from the head of Zeus. Perfection is not of man. Man's creations ripen slowly and, as man and his surroundings are ever changing, the plan which we devise for tomorrow is already incomplete by the time it is put into effect. Most criticisms that have been made of the university school of medicine have to do with defects of detail, not of principle, and where errors have been recognized they are being corrected.

The placing of the responsibility for the direction of the clinical branches on university professors whose main interest is in the development of their departments has been an unmixed blessing. The necessity for an adequate clinical staff in the university medical school is becoming generally recognized. Such a staff is far better selected by a university professor than it used to be when it flowed automatically through channels walled in by rigid rules of seniority and order of progression.

There is still room for better cooperation between university and public and private foundations in the establishment of university clinical units in general hospitals. But general hospitals are rapidly coming to realize the value of the university unit to the public, and it will not be many years before our city, state and private institutions are as generally utilized for medical instruction in this country as they are on the continent of Europe.

A criticism occasionally made of modern medical instruction is that the multiplicity and refinements of newer diagnostic methods have brought it about that the systematic teaching of the simpler procedures of physical diagnosis by experienced men has been somewhat neglected. The basis of the diagnostic art lies in the ability of the practitioner to use his five senses and properly to reason on his observations. Accurate training in those clinical procedures which can be practised without instruments or with such simple instruments as those used in auscultation and percussion, and in the ordinary routine examination of eyes, ears, throat, blood, and of the secreta and excreta, is fundamental. The art of using one's eyes and ears and hands skilfully, and of reasoning intelligently on the information so gained, the art of physical diagnosis in the stricter sense, can be attained only by the efforts and experience of the individual; it cannot be gained by reading books or listening to lectures. But it is not likely to be attained by the individual without assistance; it is not likely to be attained unless the student is, to a considerable extent, guided by teachers who, themselves, are adepts. In these days of more or less necessary specialization, the physician whose main interest lies in the chemical or bacteriologic or serologic problems of pathology—I use the word in its proper sense of the study of disease, not pathologic anatomy—is not likely to be a skilled physical diagnostician as well. It is important, necessary indeed, that the student should be led into his study of physical diagnosis by experienced and expert diagnosticians. Such training requires considerable time. This is a part of the medical curriculum which cannot be restricted. In like manner the simple laboratory methods referred to above, methods with the technique of which every physician must be thoroughly at home, cannot be taught by demonstration. The student must practise them himself under the observation and control of experienced teachers and should be required to satisfy his examiners of his thorough familiarity with them.[5]

---

[3] Ames, Joseph S.: Address on Commemoration Day, Feb. 22, 1932, to appear in Johns Hopkins Alumni Magazine, 1932, vol. 20.

[4] Thayer, W. S.: Remarks on the Occasion of the Dedication of the Colorado General Hospital and School of Medicine on Jan. 23, 1925, Colorado Med. **22**: 158, 1925.

The teaching of physical diagnosis is not merely a question of the inculcation of a technique; the student should be led systematically to work out for himself the diagnosis of each one of the important pulmonary and cardiac lesions from signs observed by him or elicited by his technical skill in auscultation and percussion and interpreted by sound physical reasoning on the basis of his own pathologic knowledge.

It may be true that in some modern schools this fundamental training has been somewhat neglected because of the multiplicity of newer diagnostic refinements the application of which is easy and convenient in the university hospital but difficult in private practice. Important as these refinements may be, they are but complementary to the information gained by a thorough physical examination, and valueless to him who cannot stand on his own feet. Every graduate of medicine should be adept in the art of physical diagnosis and at home with the simpler laboratory technique.

A criticism of American medical teaching which is not uncommon is that we are bound too closely by rigid curricula. In the continental universities the student approaches medicine in an atmosphere of freedom. He is not hampered by the necessity of following his course in a class which is subjected to examinations at stated intervals, which flows through the school, as it were, in a stated number of years, with which he must keep pace under the penalty of being obliged to abandon medicine—for it is almost this. While the amount of work which he must do is prescribed, yet he may pursue his studies as deliberately as he will. With us he is treated almost as a schoolboy and must pass, in a prescribed period, through a prescribed course. This has seemed to some[6] unfortunate, and many have looked forward to the day when the student may take his time, passing from school to school as he will, and pursuing his course under such instructors as he may choose.

This has not been possible in the past, owing, largely, to the lack of standardization of our schools, and because in many, with the limited clinical advantages, the class system is necessary, for the size of classes must be limited. Gradually this, too, is changing, and already, among the better schools of medicine, men in good standing find it easier to move from school to school; but it has not been possible as yet to abandon the class system. Another defect of the class system is that, with a four years course, it is quite impossible to cover so large a part of the field of medicine as one would. It is a pity that, if the student so desires, he may not spend a longer period as an undergraduate and give more time to the study of special branches of medicine or surgery before taking his degree. In a four years course, however, we can offer opportunities to acquire a good basis only in the main branches of medicine, and, as it is impossible to give more than a smattering of instruction in *all* the special branches, there must be a good deal of elective freedom. In some schools this has been extended to a considerable degree.

Interestingly enough, the response of students to this increased elective freedom has brought home to some observers the relative immaturity of our students, and has impressed on them the realization that, with our present premedical requirements, the student who enters even our better schools, is, very often, at a stage of educational and mental development in which he needs careful guidance and advice as to the character and sequence of the courses which he selects.

This has been emphasized by Rich[7] who wisely, points to the deplorable lack of significance of our American A.B. and S.B. degrees which are accepted as qualification for admission to some schools. We have been in the habit of assuming that he who has the degree of A.B. is necessarily an individual with the basis of a liberal education, and of a maturity which should enable him to plan his course in life with assurance.

Too often he is rather immature, commonly with an imperfect grasp even of his own language; frequently he has not yet learned how to work and is sadly in need of guidance. This is due to two main circumstances: First, in the words of Flexner,[8] "Intellectually and culturally we are not on a par with older nations, and we could not possibly be." The proportion of young people who have been brought up in an atmosphere of culture and scholarship is much smaller here than in England and France.

Second, the standards of our teaching in primary and secondary grades are below those of European schools. How many of us in this hall were taught in our early years by scholars?

The change will come with time, but, at the moment, we have to do in our universities with boys considerably less mature than those of the same age in Britain or on the continent. Self assurance is sometimes an evidence of youth. "Sophistication is not education."[9] We may like to think of them as men qualified to plan and choose their own course. Often they are not. Many need not only guidance, but supervision.

When the time arrives that secondary teaching becomes recognized with us as a dignified career commanding a proper stipend; when, in our public and private schools, our boys begin to come under the influence of scholars whose heart is in their work, rather than young men and women teaching more or less up to the limits of their knowledge, then the change will begin—and not until then.

In the meantime, without abandoning our ideals, we must recognize existing conditions. I agree with Rich in feeling that, while giving to our students so much liberty as is possible, we should not fail to see to it that they are carefully advised and guided through the too short years of their undergraduate study.

---

[5] No student should be allowed to graduate who is not skilled in the preparation of, and familiar with the examination of, specimens of fresh blood—a procedure as simple as it is important, an essential part of the initial examination of every patient, which can be carried out at the bedside or in the consulting-room in a few minutes; a procedure which is almost forgotten in some modern clinics.

[9] Rutledge, B. H.: In conversation.

Further, it is extremely important that in selecting university professors we remember that while occasionally a berth must be reserved for the rare student and investigator who needs protection and, as it were, an asylum in which to pursue his exceptional research, yet, in most instances, the abilities of the candidate as an inspirer and a leader of men, as a teacher in the best sense of the word, his character and his personality should never be forgotten. Not for his discoveries or his publications alone should a man be made a professor of medicine.

Perhaps I may be forgiven for speaking here of another element which is commonly deficient in the education of most American students of medicine. This carries us again outside of medical teaching proper, back to the common school. I shall, however, try to show that it has an influence on the capacity of the student to make the most of his opportunities in the school of medicine as well as in his broader human relations. I refer to the imperfect training of our youth in ancient and modern languages. I may approach the question from a standpoint which will seem to some to be far-fetched.

The better American medical literature has, in the past, been especially notable for its freedom from Chauvinism and from those odious and petty and childish quibbles as to priority which are so common in some communities. This happy characteristic of our literature has, I think, been in part due to the beneficent influence of the Surgeon General's Library with its *Index Catalogue* and the allied *Index Medicus*. We have usually been familiar with the literature, and we have given credit to foreign authors.

There has been another influence which has helped to bring this about, namely, that so large a body of young men who, later, have become productive students, have spent considerable periods of time in European universities and hospitals, thereby acquiring familiarity with foreign languages and literature, and, especially, forming close and cordial relations with their European and Asiatic confrères. The number of American medical students in continental universities has been traditionally large. To the student of medicine the chief value of a sojourn in foreign clinics is, precisely, the familiarity which he acquires with the language, the characteristics, the habits and the point of view of other peoples, and the personal acquaintance with foreigners who have like scientific or artistic interests.

But a few years ago the opportunities in clinic and in laboratory in the great European centers were so much better than in this country that it was highly desirable, if not necessary, from the standpoint of the scientific advantages alone, for the American student to seek the benefits of foreign study. Today, in a general way, these opportunities are as great here as in Europe, and while many American students travel, a relatively large proportion of them spend so short a time abroad that they fail to gain that familiarity with European methods and languages which was acquired by the fortunate few in the past. The number of young American medical men who come back steeped in the traditions of the continental centers, and with the foundations of lifelong friendships, is relatively smaller than it was forty or fifty years ago. This is not as yet offset by the gratifying number of foreign post-graduate students who are seeking our clinics and laboratories. These international social relations between medical men are of more than mere medical value. International professional relationships play a real part in bringing closer together the peoples of the world.

Is it not, then, important that we should bear in mind the value of international cooperation in medicine, that we should make every effort in our schools and colleges, that he who is preparing for the study of medicine may acquire a better linguistic foundation? Ought we not to look to it that the circumstance that our standards of medical education are higher, and that important original investigations are being carried on in many centers in this country shall not lead us to a subconscious sense of independence of the work done by our colleagues on other continents? Should we not make every effort to insist on a knowledge of French and German, to impress on the student the desirability of cooperation with workers in other countries, the value of the establishment of direct relations with them and the duty of familiarity with and recognition of their work?

The barrier of language is a sad hindrance to progress; it is, alas, responsible for many of our international misunderstandings, personal, political, scientific. Most men have much in common. When we meet and commune freely, one with another, we quickly find points of contact, and very often conceive a sincere admiration for those elements of special excellence which we are sure to discover in our neighbor. Fatally separated by the barrier of language, we are very likely to be as jealous and suspicious as dogs—for men are singularly like dogs. The serious student of medicine should be able to read, in the original, the important literature and textbooks in French, German and English.

Is not this largely provided for by the higher requirements for admission to our medical schools? Is it not true that far more students read French and German today than in 1903? Do not the requirements to enter a good college or university "insure a sufficient knowledge of the ordinary school branches and also Latin or Greek?" Alas, I fear that this is far from true.

The currents and countercurrents in modern education are baffling. Along with the improvement of our schools of medicine and the increased cultivation of the natural sciences, there has been in this country and, to a considerable extent in other countries, a remarkable neglect of the teaching of languages in the early school years. This is not the place to enter into a discourse on the teaching of language, but it may not be out of the way to observe that from fifty to seventy-five years ago the early teaching of the classics, especially Latin, supplied to those who sought a good general education, as it does in the better European schools today, that fundamental understanding of grammatical principles which went so far toward improving their comprehension of the niceties of the mother tongue, quite apart from its cultural value in other respects.

An early familiarity with the classics, acquired in his youth, gave the student of the middle of the last century an innate sense of the significance of those roots on which, for convenience's sake, is based our entire scientific terminology, precisely in order to make it more comprehensible. For at that time and for many centuries a certain acquaintance with Latin and Greek was the common possession of all educated men. To the boy who studied the classics, especially Latin, early in his career, the study of English grammar was unnecessary and superfluous. I remember well my mother's surprise and indignation when she found that, at a little private school to which I was sent fifty-eight years ago, instead of beginning the study of Latin I was to be taught English grammar. By the young languages are acquired naturally and easily. The early study of Latin is the very best way to improve one's English and to make easy the comprehension and acquisition of foreign languages, especially the Romance languages. Latin, properly taught, is not a dead language.

Within a few generations the teaching of the classics has been so far abandoned in this country that it is really difficult, if not impossible, to find suitable teachers for many schools in which Latin and Greek are still taught.

The abandonment of the classics is, probably, in considerable part responsible for the relative immaturity of the American youth of today; it has led to some amusing manifestations. Ignorant of the classics, unaware that Latin was but yesterday the common language of science, confused by scientific terminology, worthy men[10] now and then call for its simplification, suggesting that scientific terms be translated into the vernacular. At the same time, annoyed by their incomprehension of foreign tongues, when they seek to read the works of others, they propose, in bland and blessed innocence, the re-creation of that which their fathers threw away, a common language of science.[11] In two generations we have come full circle!

It may be paradoxical but it is true that along with our increased self-sufficiency from a medical standpoint, with the abandonment of the fundamental teaching of the classics, with the increasing nationalism which has followed the World War, the ability to read French and German which has always been required of students in the school of medicine with which I am connected has become less general. Thirty years ago the only textbook which I used in one of my courses was a German work which had never been translated into English. This would scarcely be possible today. Whatever our attitude may be toward the teaching of the classics, it is of the greatest importance that we insist on a reading knowledge of French and German in our students.

With regard to the classics: As one whose fundamental classical education was but mediocre, but as one who has associated from boyhood with those whose classical foundation was good; as one who has lived in a period in which the classics are sadly neglected in our public, as well as in most of our private schools, I have no hesitation in saying that in my opinion the early study of the classics under scholarly teachers is time saved, not time wasted, for one who would have a good general education; there is no better mental training, and the introduction, through the classics, to the history and traditions of European civilization is of unique cultural value.

There is no training better for him who is to pursue a scientific career than that which leads to the early acquisition of the rules which govern the grammatical construction of Latin and Greek and, secondarily, of our own tongue. The neglect of the classics has not improved the use of English by the present generation. Language is the mirror of thought.[12] He who is incapable of expressing his thoughts clearly is incapable of thinking clearly. Subtlety of thought and subtlety of language are one. "The man of science," says Clifford Allbutt, "ought best to know that style and matter can no more be dissociated than skin and bone; that if we write clumsily, loosely, or disjointedly our thoughts are accordingly."[13] Nothing has been substituted for the early study of the classics that takes its place from a disciplinary standpoint. No time need be lost. The basis of the understanding of language and the conceptions which go with it was, should be, and may easily be laid before the age at which the study of the natural sciences can profitably begin. It is very largely the early teaching of the classics and the early and careful attention given to language that distinguishes European secondary education from ours.

Here in America we shall have to begin again. There are few secondary schools in which the classics are adequately taught today, few universities in which the classics are taught other than as a subject for philological, historical, or archaeological research or for the training of teachers.

I should not be surprised to see the development before long, among secondary schools, of special centers in which more attention is given to the early and thorough teaching of the classics. I am inclined to think that training and discipline in language will become more generally recognized than it is today as a necessary requirement for him who is to enter on a scientific career.

Prompted by a consideration of the words of our dear friend and master, I have indulged in a few reflections on modern American medical education. We have seen how many of the reforms that he foresaw and advised have come to pass. May he who has played so large a part in this progress long be spared to guide us with his wise counsel!

---

[10] Within a few months an amusing editorial on this subject appeared in one of the leading New York daily papers. The writer seriously complained of the barbarous and incomprehensible terminology of medicine.

[11] In the Baltimore Sun of Feb. 20, 1932, there was an item with a rather flaring headline, "Universal Language Discussed," in which the statement is made that Dr. Alfred D. Flinn, director of the Engineering Foundation of New York City, "in a recent 'Research Narrative' of that organization" has set forth "specifications for a new universal language for scientific, political and business purposes. . . . The sounds of the new language should be easily learned by either children or adults, by personal instruction or by mechanical aids such as sound pictures or phonograph records. Grammatical forms should be simple and uniform. . . . Exactness and clarity are the chief necessities, leaving to existing languages the expression of emotions in poetry, literature and drama. . . . One specification yet to be decided, Dr. Flinn tells, is how low a level of average intelligence the new language needs to fit."

Proposed Postulates for Filtrable Bacteria.—In order to truly demonstrate the principle of a cycle between filtrable and nonfiltrable—or, more exactly, large and minute forms of a morphological cycle, we would set up the following postulates: (1) It must be possible to filter a suspension of a well defined pure culture of bacteria through a filter which holds back the characteristic forms; and these original forms should not appear in the filtrate or in cultures made with adequate amounts of the filtrate on suitable media after incubation of at least two or three weeks. (2) There must be evidence of growth of some kind in cultures made of this filtrate, but without evidence of the presence of the original normal forms. (3) The culture of the filtrable or minute form must be carried in a series of several generations. (4) It must be possible to recover the normal forms from such successive "filtrable attributes." Such requirements have not, as far as we know, been fulfilled by Mellon, by Rosenow or by Kendall, who are among the chief protagonists of the existence of filtrable stages. They have been reported, we believe, only by Hadley, who gives details in regard to his Shiga bacillus filtration, but this work has not yet been sufficiently confirmed.—Zinsser, Hans: On Postulates of Proof in Problems of the Bacterial Life Cycle, *Science* **75**:256 (March 4) 1932.

PAINFUL ANEURYSMS OF THE AORTIC ARCH

RELIEF BY PARAVERTEBRAL INJECTIONS OF PROCAINE AND ALCOHOL

JAMES C. WHITE, M.D.
BOSTON

Aneurysm of the arch of the aorta, when it begins to erode the sternum and to compress the structures at the apex of the thorax, may give rise to excruciating pain. It is then a most distressing condition and one which the physician has been able to do very little to alleviate. Mere palliation of this agonizing pain gives the greatest comfort to these sufferers. But patients in the terminal stages of aortitis are no candidates for radical neurosurgery, so that any surgical intervention must involve the minimum operative shock. Such cases probably constitute as poor operative risks as advanced cases of angina pectoris. The statistics of cervical sympathectomy in the latter condition reported by Fontaine[1] and Cutler[2] show a mortality of from 8 to 21 per cent. On the other hand, paravertebral injection of the upper thoracic sympathetic ganglions, first described by Mandl[3] and further developed by Swetlow,[4] White,[5] Woodbridge[6] and others, has recorded to date a series of more than 100 cases with no mortality and very satisfactory results. I[7] have felt from the beginning that the fundamental effect of this procedure was the blocking of afferent painful pathways. With an experience in twenty-five cases of angina pectoris and believing that the nerve supply of the aortic arch is very similar to that of the heart, it was a natural step for me to try the effect of paravertebral injection in cases of painful aneurysm.

I[7] have recently reviewed the anatomy of the pain pathways from the heart and upper aorta. Briefly, afferent impulses leaving the heart and proximal aorta may follow two different routes: they may either ascend the middle and lower cardiac nerves to the corresponding cervical sympathetic ganglions, whence they descend in the sympathetic trunk to the upper dorsal ganglions, or run directly across the posterior mediastinum to these same ganglions. Thence the impulses traverse the white rami communicantes to enter the dorsal root ganglions of the upper thoracic spinal nerves. From this point, according to the theories of Head and Mackenzie, conscious pain is referred to the corresponding dermatomes and carried to the sensorium over somatic afferent pathways. It is therefore evident that the most accessible point at which these visceral pathways can be successfully blocked is the upper dorsal sympathetic ganglions or their white rami.

Surgical experience has shown that cutting the vagi or the intercostal nerves has no effect on cardiac pain, and also that removal of the entire cervical sympathetic trunk is frequently ineffective. On the other hand, resection of the upper thoracic ganglions has been uniformly successful in four cases reported from this clinic;[7] and in each case in which objective evidence has shown a successful injection of these structures, the pain of angina pectoris has disappeared.

Evidence acquired by the application of paravertebral alcohol block to three cases of painful aortic aneurysms has shown it to be effective. In reporting these cases I shall not attempt to detail the method of paravertebral injection, which is explained in Labat's textbook[8] and in the papers already referred to. It would be well, however, to mention the value of preliminary injections with procaine, to determine which segments carry the painful stimuli, prior to the injection of alcohol. Diagnostic injection of the sympathetic rami and ganglions with procaine, as described elsewhere,[9] has proved to be of the greatest value in this condition, as the pain was referred over a large number of dermatomes and yet could be blocked by infiltrating only the upper two thoracic ganglions and their communicant rami. In each instance there was an immediate cessation of pain, and injection of alcohol was therefore limited to these two segments.

REPORT OF CASES

Case 1.—James E. B., aged 48, a native American railroad conductor, contracted a penile chancre in 1901. He had no treatment until 1926, when he first noticed pain in his right shoulder and dyspnea on exertion. A Wassermann test of the blood was then strongly positive. Physical examination showed his heart to be enlarged to the left and downward. There was a loud systolic murmur at the base, transmitted into his neck, as well as loud systolic and diastolic murmurs at the apex. The ascending aorta was expanded into a large aneurysm, with some dilatation of the innominate artery as well.

Subsequent to this examination he was followed in the outpatient department and treated with potassium iodide, quinine bismuth iodide, and mercurial ointment. He found lighter work as a railroad clerk and felt well until June, 1929. He then began to be troubled by palpitation on exertion and periods of syncope. Three weeks before his admission in January, 1930, he caught cold and developed a dry hacking cough. A week later he began to suffer extremely from pain behind his right ear, running down his neck over the right shoulder and upper part of the chest. This pain was constant and burning in character and became intolerably severe when he coughed. His cough became dry, nonproductive and brassy.

The patient was obese, with a cyanotic, swollen face. There was a bulging pulsating tumor rising above the right side of the manubrium and the medial half of the clavicle. The heart conditions were similar to those at his previous examination. The right radial pulse was greatly diminished, and blood pressure reading on the two sides showed a pressure of 85 systolic and 70 diastolic on the right and 115/80 on the left. The Wassermann and Hinton tests of the blood continued strongly positive. Roentgen examination showed a great increase in the size of the aneurysm, which now involved the entire ascending aorta and the beginning of the great vessels (fig. 1).

Antisyphilitic measures having been pushed to the limit without relief, it was essential to do something to palliate the pain. The wide area over which this pain was referred is shown in figure 2. From this it is apparent that the segments involved extended from the first cervical to the third dorsal. As there were no previous reports in the literature, it was necessary to determine in the first place whether the painful impulses were transmitted over the cervical and upper dorsal spinal nerves, or whether they entered the cord through the

sympathetic rami. In the former case laminectomy and section of multiple posterior roots would have been necessary, a procedure which the patient would obviously not have tolerated. On the other hand, if the pain traversed the sympathetic nerves, the point of entry into the spinal cord would be concentrated in the upper dorsal segments, as explained in the beginning of this article.

Feb. 7, 1929, diagnostic blocking of the first and second dorsal sympathetic ganglions clearly proved this to be the case by relieving his pain entirely for thirty-six hours. Five cubic centimeters of 95 per cent alcohol was then injected paravertebrally into each of these areas. This produced a small band of anesthesia reaching across the upper part of the back into the axilla, which disappeared in two weeks. There were no troublesome sequelae. The patient was totally relieved of all his pain and was discharged two weeks later.

He remained free from pain for four months. He then reentered the hospital decompensated and died suddenly of rupture of his aneurysm. An autopsy was performed and showed a huge aortic aneurysm which had ruptured anteriorly. Examination showed two small retropleural scars about 1.5 cm. in diameter. These surrounded the first and second intercostal nerves at their point of emergence from the intervertebral foramina, their communicant rami, and the corresponding sympathetic ganglions. While the intercostal nerves themselves and the ganglions did not show histologic evidence of degeneration, the communicant rami appeared to have been destroyed.

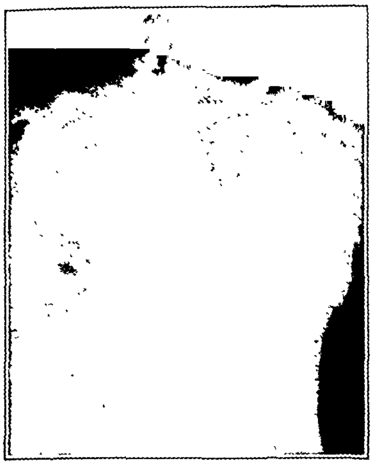

Fig. 1 (case 1).—Aneurysm which involved the ascending arch of the aorta and the origin of the great vessels in the neck.

Case 2.—Antonio C., aged 54, an Italian farmer, who had always considered himself well and strong, had, however, noticed a penile sore at 18, which had been treated only by local applications and pills. Seven months before admission he noticed a slight cough and then twinges of pain in the left side of the chest accompanying the cough. The pain shortly began to radiate down the inside of his left arm, to the left scapula, and both sides of the neck. During the past three months the pain increased to a steady discomfort over the regions noted. Three weeks before he had noticed a swelling of the upper left part of the chest, which became tender and sensitive to touch. He was brought in to the outpatient department, where a diagnosis was made of late syphilis with aneurysm of the transverse arch of the aorta. Local examination showed a large, bulging, pulsating mass, 7 cm. wide, just to the left of the upper sternum (fig. 3). There was a harsh systolic murmur over the tumor, but the heart itself was not enlarged and showed no evidence of valvular disease. Blood pressure in the right arm was 130 systolic and 86 diastolic and in the left 90/?. The patient also showed a well marked Horner's syndrome on the left side from pressure on the thoracic sympathetic fibers. There was no evidence of involvement of the central nervous system. Both the Hinton and Wassermann tests were strongly positive.

A roentgenogram of the patient's chest (fig. 4) showed the heart measurements to be within normal limits, but the supracardiac dulness was about twice the usual size. Lateral views showed a rounded mass in the region of the arch of the aorta, which showed true pulsation. The patient was observed in the ward for four days and suffered acutely and continuously from pain over the area described. This could be relieved only by one-fourth grain (0.016 Gm.) doses of morphine given at frequent intervals.

As no direct operative attack could be made on an aneurysm of this size and position, it was decided to do a procaine injection of the thoracic sympathetic fibers in order to determine whether it would be possible to relieve the pain by blocking these structures.

Oct. 22, 1930, paravertebral injection of procaine was done beneath the first and second ribs on the left side; 5 cc. of 2 per cent procaine epinephrine solution was injected against the vertebral bodies in the region of the vertebral foramina. This gave immediate relief from all pain and hyperesthesia in the painful area.

Much to our surprise, the pain failed to recur as the procaine was absorbed, so that at the end of a week the patient remained completely pain-free. He was discharged with the understanding that he was to have antisyphilitic treatment in the outpatient department and to reenter the hospital for alcohol injection if the pain returned. Following his discharge he reported complete relief for three weeks. Then for a period of two weeks the pain recurred. He was considering reentry for alcohol injection when the pain again disappeared spontaneously. He finally developed bronchopneumonia and died painlessly, Jan. 10, 1931, of a sudden hemorrhage following a coughing spell.

Prolonged relief of pain following simple procaine injection of the painful nerves has been reported on numerous occasions, notably by Mandl,[3] who uses this method as a routine for relief of angina pectoris. There have been several instances in this clinic of prolonged and severe visceral pain which have been completely relieved by procaine for long periods of time. Usually, however, the pain has recurred in from two to thirty-six hours, necessitating a second injection with alcohol.

Case 3.—Eric N. S., aged 37, a Swedish carpenter, stated that he had always enjoyed excellent health. Seventeen years before, while he was working as a seaman, he noticed a "red pimple" on the penis. This had appeared about three weeks after his last exposure to venereal infection. He then noticed a swollen gland in the right groin. The penile lesion was treated several times by the ship's captain with local applications. The patient felt bad for about a month but does not remember skin lesions or other sequelae.

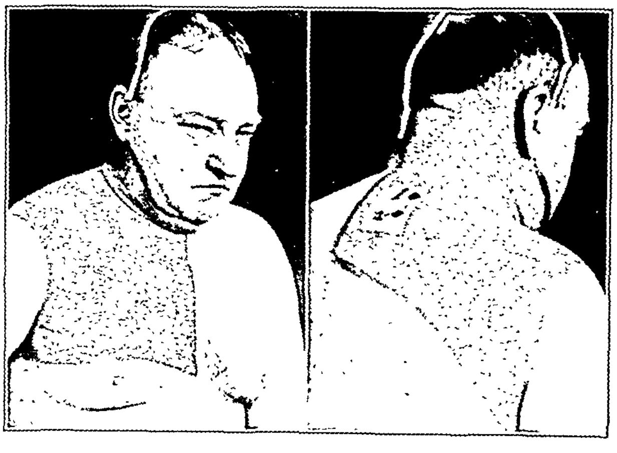

Fig. 2 (case 1).—Area of referred pain from aneurysm of ascending arch of aorta, and points of injection that gave relief.

In 1925 the patient came to the hospital complaining of cough, dyspnea on exertion, dysphagia and precordial pain of nine months' duration. These symptoms had appeared suddenly after a heavy blow on his left shoulder. Examination at this time showed only slight enlargement of the heart, but an increase in supracardiac dulness to 8.5 cm. Blood pressure could not be obtained in either arm, but in the popliteal space it was found to be 240 systolic and 170 diastolic. The Wassermann reaction was strongly positive. Roentgen examination revealed a supracardiac shadow 8 cm. in diameter, which displaced the trachea slightly to the left but did not pulsate. It did, however, appear to be continuous with the heart. The patient had a series of antisyphilitic treatments in the outpatient department for the next five years.

During the period after his first admission the patient had frequently been bothered by pain over the upper precordium, which extended occasionally to the axilla and into the neck on the left side. It was dull but increased on exertion. The palpitation and dyspnea improved considerably on antisyphilitic measures. During the past year, until two weeks before admission, the pain left him almost completely. Six months before, following a severe cold and cough, he noticed the development of a lump in the suprasternal area. Two weeks before admission another severe cough and cold came on, and the pain in the chest reappeared with great severity. For the first time he noticed hyperesthesia over the anterior left upper part of the chest associated with a sharp, burning, drawing pain in this region. Five days before admission the tumor at the upper end of the sternum enlarged considerably and became very tender.

The patient was well developed and well nourished, with flushed cheeks, he was apprehensive and in considerable pain. The heart was greatly enlarged to the left, and the supracardiac dulness measured 9 cm. The heart sounds were of poor quality, they were regular, and there was a soft, blowing systolic murmur over the whole precordium, heard best at the apex. There was also a loud to-and-fro murmur over the tender swelling in the upper sternum (fig. 5). Blood pressure could not be obtained in either arm. The left arm could not be abducted on account of the severe pain in the left clavicle and the left anterior side of the chest. A definite tracheal tug was made out and a diastolic shock over the tumor mass. Both the Hinton and the Wassermann reaction of the blood were still strongly positive, but there was no evidence that the central nervous system was involved. By roentgen examination the mass in the upper mediastinum showed a slight but distinct increase in size and appeared to pulsate slightly (fig. 6).

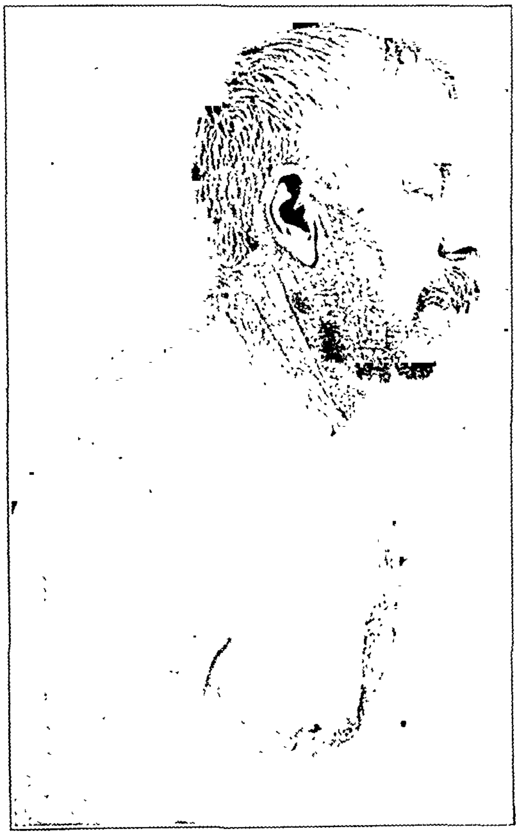

Fig. 3 (case 2).—Aneurysm of aortic arch eroding through the upper part of the sternum.

Dec. 4, 1930, paravertebral injection of procaine was given, followed by 5 cc. of 95 per cent alcohol in the region of the first and second thoracic vertebral foramina on the left side. This gave immediate and complete relief of the patient's pain and hyperesthesia, which has lasted to date, a period of twelve months. The patient has reported back to the clinic from time to time and has shown a gradual diminution in the size and pulsation of the substernal mass. Although he is still unable to work on account of dyspnea and easy fatigability, yet he has shown a marked improvement in his general condition and is extremely happy over the success of the injection treatment for the relief of his pain.

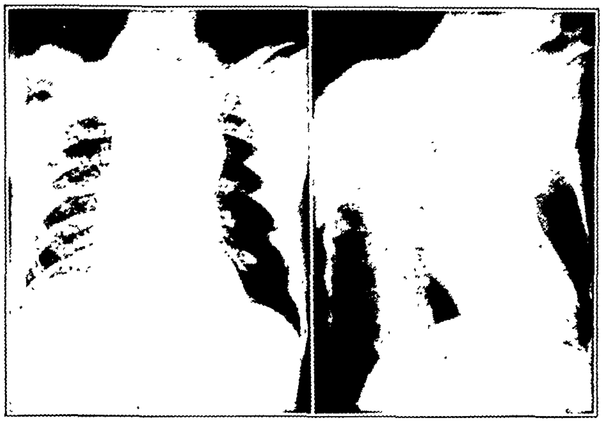

Fig. 4 (case 2).—Extent of aortic aneurysm.

COMMENT

In the three cases reported, the relief of intense suffering was highly satisfactory. In the two patients injected paravertebrally with alcohol, no further pain was noted; in the third, in whom procaine alone was used, pain totally disappeared for three weeks, recurring only in minor transitory attacks, so that a further injection with alcohol was never considered necessary. Why injections of procaine alone should give more than an hour or two's relief from visceral pain cannot be adequately explained, but Mandl[3] has reported relief of angina pectoris lasting for weeks and even months. After a successful injection of alcohol, the result seems to be permanent. I have a patient with angina pectoris who has gone for nearly five years without an attack on the injected left side, although he continues to have minor right-sided attacks, which have naturally not been affected by the injection of the sympathetic nerves on the left. In the third case reported, the patient remains well and free from pain at the end of a year.

That an accurate injection of these structures, which lie at a depth of from 5 to 8 cm., requires considerable technical skill goes without saying. The accuracy of the injection in the first case was shown by the final autopsy. The experience in these three cases would make paravertebral injection in aneurysm appear rather easier than in angina pectoris, probably because only two rami instead of four or five need to be injected. Another encouraging feature in this limited group of cases is that the rather general complaint of hyperesthesia of the overlying intercostal nerves, which has been a distinct annoyance in most of the angina cases following alcohol block, has been notably absent.

To digress from the purely clinical side of this paper, a point of much theoretical interest is that the mechanism of relief of pain in these cases must lie in the blocking of afferent pain pathways in the sympathetic system. Proponents of the theory that the sympathetic nervous system exerts primarily a motor influence on the viscera have frequently stated that blocking the sympathetic pathways in angina pectoris prevents the attacks by inhibiting vasospasm of the coronary arteries. No such possibility can be evoked here, where the pain of distention of the aneurysm and pressure on the surrounding viscera is of a constant, steady nature. Weiss and Davis[10] have shown that visceral pain can be relieved by infiltrating the skin segments to which that pain is referred. It might be felt that as the upper two intercostal nerves are anesthetized in this procedure, the cessation of the pain might be caused by blocking the somatic half of the viscerosensory reflex. This theory, however, is untenable, as the anesthesia of the intercostal nerves never lasts more than a few weeks.

CONCLUSION

I would like to emphasize that the paravertebral injection of alcohol is a poor substitute for sympathetic ganglionectomy in any patient who is a reasonably good operative risk, on account of the technical difficulty of jecting the alcohol with sufficient accuracy to be cer-in of destroying the ganglions or their communicant ami. However, in such cases as those reported, in which there are rapidly enlarging aneurysms, the dangers of cardiac decompensation, respiratory obstruction, or rupture of the aneurysm make a radical operation on the stellate and second dorsal ganglions quite out of the question. In these, however, paravertebral injection can be done with reasonable safety and a good chance of lasting relief of the chief complaint—pain. While actual prolongation of life is not to be expected from the relief of pain, it may be brought about indirectly by permitting the exhausted sufferer to rest and sleep in relative comfort.

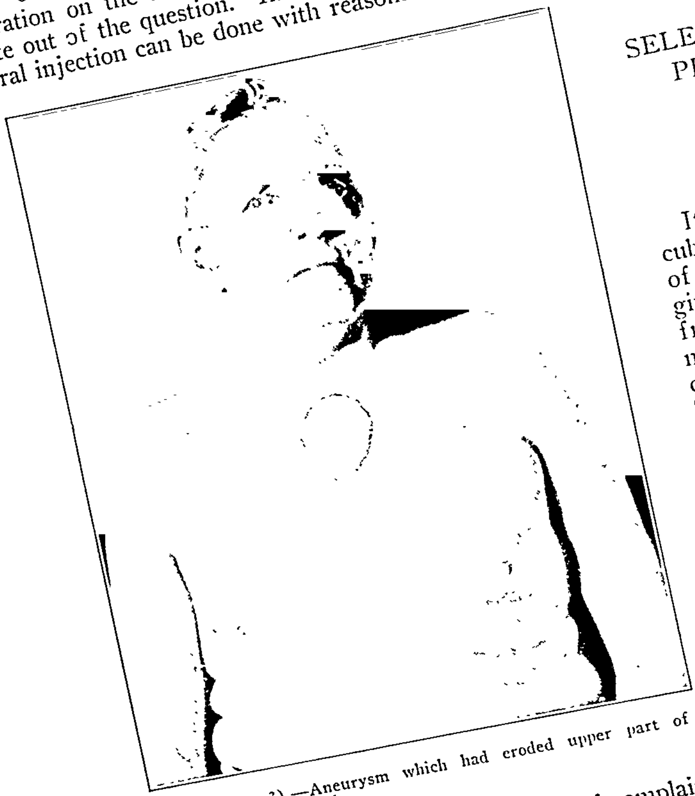

Fig. 5 (case 3).—Aneurysm which had eroded upper part of the sternum, marked by circle.

SUMMARY

1. In three cases reported, successful relief of pain was obtained in advanced aneurysms of the aortic arch.

2. The intense suffering that may occur in this condition, as well as the cardiac pain of angina pectoris, can be relieved by paravertebral injections of procaine or alcohol.

3. Procaine injection is of diagnostic value in determining which communicant rami transmit the painful impulses to the spinal cord. It may give relief over prolonged periods.

4. Alcohol, when accurately injected, causes permanent destruction of the sympathetic rami.

5. Sympathetic ganglionectomy, although a surer method of interrupting cardio-aortic pain pathways, is too serious an operative procedure to use in patients with large thoracic aneurysms. Paravertebral block, although technically a difficult procedure, is well tolerated and should give satisfactory results in a large percentage of cases.

SELECTIVE COLLAPSE OF LUNG WITH PHRENICOTOMY COMPARABLE TO THAT WITH PNEUMOTHORAX

C. M. VAN ALLEN, M.D.
PEIPING, CHINA

It is commonly appreciated that when a few hundred cubic centimeters of air is injected into the pleural space of persons with tuberculosis of one lung lobe, the slack given by the air to the elastic pull of the hemilung is frequently taken up more by the diseased than by the normal lobes, with the result that the air resides principally over the diseased lobe and collapses it selectively. The roentgenographic appearances in one of these cases are shown in figure 1. The exposure at *A* was made of the chest before induction of pneumothorax and demonstrates the presence of a tuberculous lesion lightly infiltrating the right upper lung field; that at *B* was made immediately after the last of a series of injections, which introduced 800 cc. of air and occupied ten days and shows marked collapse of the diseased portion of the lung without detectable deflation of the normal portion; and that at *C* was taken a few days later, after introduction of much more air, and demonstrates uniform and complete deflation of the hemilung. The phenomenon in reference is shown in the second roentgenogram and is termed selective collapse or selective pneumothorax.

Figure 2 is used to illustrate the principle of differential elasticity of the lung commonly believed to explain selective collapse after pneumothorax, so that certain comparisons can be made later. It shows three views of a rectangular frame which represents the walls of a hemithorax. Two rubber bands are stretched the width of the frame, to represent the upper and lower pulmonary lobes, being fixed directly to the frame on one (the left) side as lobes are fixed to the mediastinum, and being connected indirectly to the frame on the other side with bracket and cord, the bracket representing the lateral surface of the lung and the cord the pull of the intrapleural suction. The bands are the same length when completely relaxed but the upper band has the greater thickness and elastic tension; which circumstances imitate those of the pulmonary lobes when the upper one is tuberculous. The bracket has pivoted bars at each end, which serve for attachment of the bands and represent the lateral surfaces of the two lobes. The cord runs from the center of the bracket to the center of the frame's side, so that its pull is evenly balanced like that of the intrapleural suction. In the view at *A* the bracket is completely drawn to the frame in imitation of the situation in figure 1 *A*. At *B* the cord is released a little, and the result is that the upper band is much shortened while the lower one is scarcely shortened at all. This may be compared to the condition in figure 1 *B*. Further release of the cord, as shown at *C*, relaxes the bands completely and brings them to equal lengths. This is similar to the condition in figure 1 *C*.

Surgery, Peiping Union Medical College.

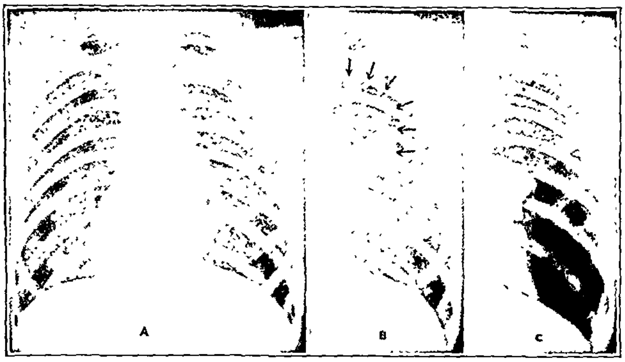

Fig. 1.—Appearance of lung in patient with tuberculosis involving the right upper lung field, in whom the diseased tissues collapsed selectively after pneumothorax: *A*, entire chest before pneumothorax; *B*, after injection of 800 cc. of air (arrows indicate selective collapse); *C*, after complete pneumothorax.

Several authors have called attention recently to the fact that after phrenicotomy for pulmonary tuberculosis the diseased part of the hemilung may be favorably affected regardless of its position; whereas it was the belief of those who first employed the treatment that it benefited only lesions situated in the lower lobes. Thus, O'Brien[1] found in a large series of cases that 46.6 per cent of tuberculous cavities in the upper lung field, 62.5 per cent of those in the middle field, and 80 per cent of those in the lower field were obliterated after phrenicotomy, and he commented as follows:

> It is possible that the smaller percentage of closures of cavities in the upper lung field was due to the fact that in this region the cavities, as a rule, are larger and have thicker walls than those found at the base. Cavities at the apex are often at the periphery of the lung with the walls of the cavity adherent to the wall of the chest, so that contraction of the elastic tissue of the lung has less tendency to cause their closure. The presence of adhesions over the whole lung surface is, of course, also a factor. It is my experience that similar lesions under favorable conditions will be equally affected by phrenicotomy whether they are located in the upper or lower lung fields.

R. C. Matson[2] found that

> the results of an induced hemidiaphragm paralysis are less dependent upon the site of the lesion than upon its type. This is explained by the fact that in certain types of tuberculosis, particularly in the proliferative varieties, the collapse capacity of the diseased lung tissue is greater than that of healthy lung tissue. Therefore, even though the lesion is in the upper lobe, the rising diaphragm, by reducing the volume of the hemithorax, permits the collapse capacity of the diseased lung tissue to exert itself, even without any collapse of healthy lung tissue.

To prove his statement this author presents roentgenograms of a case before and three years after phrenicotomy in which, at first, a very large cavity was present in the upper lobe and, at last, the cavity was absent and the upper lobe was densely fibrotic and extremely shrunken. The diaphragm was much higher in the second view, but the vertical diameter of the air-containing, normal part of the lung above was not reduced. Evidently the slack given to the hemilung by the rise of the diaphragm was entirely taken up by obliteration of the cavity and shrinkage of the diseased tissues. The inference was that the shrinkage occurred over a period of three years from proliferation and contraction of fibrous tissue taking place as the lesion healed.

In the two cases to be described, selective collapse appeared very shortly after phrenicotomy, as in the case with pneumothorax, without sufficient time to allow for proliferation and contraction of fibrous tissue.

Case 1.—A man, aged 24, had had symptoms of pulmonary tuberculosis for two years. Roentgenographic examination showed that the lesion was scattered thinly over the upper and middle lung fields on the right, whereas the lower field presented no change except accentuated bronchial markings which did not appear tuberculous (fig. 3 *A*). A large cavity existed in the lower part of the middle field, close to the lower boundary of the lesion. The pulmonary environs were not distracted. The sputum contained tubercle bacilli. The right phrenic nerve was avulsed, and five days afterward the film reproduced in figure 3 *B* was taken. This showed the diaphragm and cavity to be greatly elevated, the former only a little the more, so that the vertical diameter of the hemilung was shortened much more than proportionately at the expense of the diseased segment. The size of the cavity was not changed. Figure 3 *C* gives the appearances eighteen months later when the diaphragm was in about the same position but the cavity was missing and the lesion as a whole was inactive.

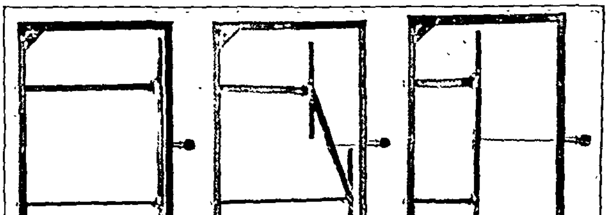

Fig. 2.—Model which demonstrates the principle of differential pulmonary elasticity responsible for selective collapse after pneumothorax.

Case 2.—A woman, aged 32, gave much the same history as the previous patient. Also, a large cavity was present in the lower part of the right middle lung field; but the parenchyma below it was infiltrated lightly with tuberculosis, while the lung above was nearly devoid of disease (fig. 4 *A*). Phrenicotomy was done on the right, and one week later the next roentgenogram (fig. 4 *B*) showed the diaphragm markedly elevated, with extremely little elevation and no appreciable collapse of the cavity. A film (fig. 4 *C*) eight months later indicated further rise of the diaphragm, closure of the cavity and fibrosis of the lesion.

[2] Matson, R. C.: Operative Collapse Therapy in the Treatment of Pulmonary Tuberculosis, West. J. Surg. **38**: 662 (Nov.), 743 (Dec.) 1930, **39**: 13 (Jan.) 1931.

Reference is made particularly to the selective collapse of the diseased parenchyma that occurred in both cases immediately after the operation. The objection could be raised in case 2 that the upper lobes may have been adherent to the chest wall and therefore could not retract when the diaphragm rose and that this, rather than differential elasticity, might explain the situation. Adhesions could, indeed, have been responsible in that case, for there is no proof of their presence or absence; but they could not have brought about the result in the first case. The author has seen other examples of this selective collapse, less extensive but equally well defined.

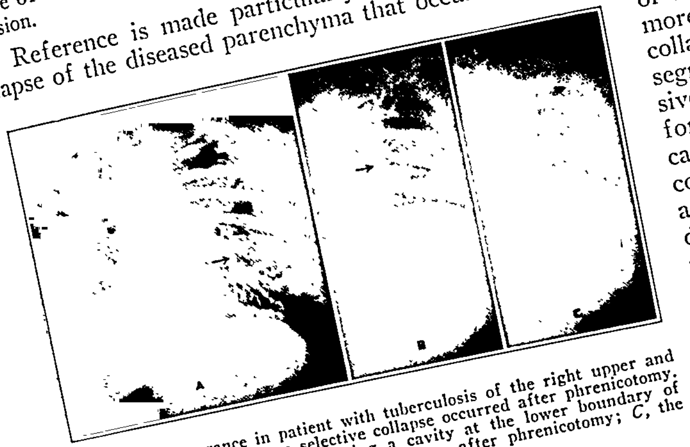

Fig. 3.—Appearance in patient with tuberculosis of the right upper and middle lung fields, in whom selective collapse occurred after phrenicotomy. *A*, entire chest, the arrow indicating a cavity at the lower boundary of the lesion; *B*, the right hemithorax five days after phrenicotomy; *C*, the same view eighteen months later.

A model has been constructed to illustrate the principle of differential elasticity which may have been concerned in the early selective collapse in these cases (fig. 5). It has a rectangular frame to represent the walls of a hemithorax. The short side below is movable and represents the diaphragm, while a rubber band, stretched from top to bottom, takes the place of the lung. The band is composed of two segments which are equal in length when relaxed but are unequal in thickness and elastic tension, the upper one being the tenser to represent a diseased upper lobe. The view at the left shows the model with the diaphragmatic side drawn to the bottom; the two series of vertical lines in the middle indicate the lengths of the two segments of the band found by measurement before, at a number of stages during, and after elevation of the diaphragmatic side; and the view at the right shows the model with the band completely relaxed. The relaxing process exhibits two distinct phases: first, one indicated at *x* with shortening chiefly of the thicker segment and, second, one at *y* with shortening chiefly of the other segment. Phase *x* appears to correspond to the phase of relaxation of the lung produced by phrenicotomy in figure 3 *A* to *B*. Although no illustration is given to show it, when the positions of the rubber segments are reversed in the frame to correspond with the positions of the normal and diseased segments of the lung in case 2, the band contracts in two phases as before. The first phase is again characterized by shortening of the thicker segment and suggests the manner of relaxation of the diseased segment of lung (fig. 4 *A* to *B*).

In proliferative pulmonary tuberculosis the scar tissue in the parenchyma tends to contract as healing progresses and, like cicatricial contraction in other regions of the body, the process requires months or years. Operations that relax the lung undoubtedly increase the contraction. Bronchial obstruction is a second cause for contraction in this disease, for when the bronchus of one or more lobes becomes obstructed, as by viscid exudate, blood clot, enlarged peribronchial lymph nodes, or bronchial cicatrix, or when the bronchus of one or more lobules within a lobe becomes so obstructed and collateral respiration is also shut off,[3] the corresponding segments of lung become atelectatic and shrink extensively. But these causes for shrinkage do not account for the selective collapse that took place in any of these cases soon after the relaxing operations, because the collapse was far too quick for the shrinkage of scar and because bronchial obstruction had not been produced. The collapse had the characteristics of elastic recoil rather than those of shrinkage of an inelastic substance.

Work just completed by Van Allen and Wu[4] demonstrates that parts of the lung infected with pneumococcus develop large increases of elastic tension as early as six hours after entrance of the organisms to the bronchi, which is many hours before blockage of the bronchioles and alveoli (consolidation); and also as late as many days after reestablishment of patency of the air passages and sacs. At these preconsolidative and postconsolidative stages of the disease, the lung shows thickening of the alveolar and lobular septums and pleural membranes from the presence of dilated vessels and interstitial inflammatory fluids and cells; and this seemed to us to be the cause for the increased resistance to inflation. Since in tuberculosis the pulmonary septums and membranes are thickened in much the same way from the earliest stages of the disease, whatever the type of lesion, it seems likely that the increased elastic tension in that disease is due somewhat to that cause. A second factor is probably the formation and contraction of scar tissue beforehand in some parts of the diseased lobe with stretching of the elastic tissues in the rest of the lobe. The extent to which the first or second cause is responsible in a given case is probably

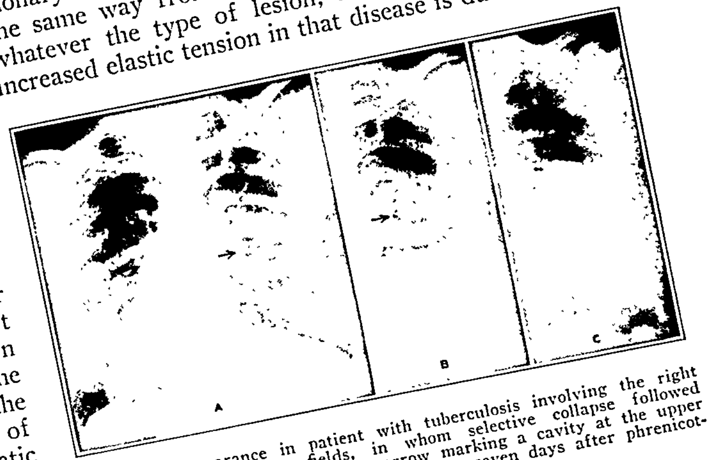

Fig. 4.—Appearance in patient with tuberculosis involving the right middle and lower lung fields, in whom selective collapse followed phrenicotomy: *A*, whole chest, the arrow marking a cavity at the upper boundary of the lesion; *B*, right hemithorax seven days after phrenicotomy; *C*, condition eight months later.

[4] Van Allen, C. M., and Wu, C.: Increased Elastic Tension of the Lung in Experimental Pneumonia, to be published.

determined by the degree to which the exudative or proliferative variety of tuberculosis happens to predominate. With essentially exudative lesions the first cause probably acts almost alone; while with the proliferative lesions, especially the early ones, both causes are probably concerned, the second being perhaps the more important.

The type of selective collapse in pulmonary tuberculosis that develops rapidly after pneumothorax or phrenicotomy probably occurs also, although to less extent, without collapsing operations, judging from the appearances presented by certain cases in my experience. In one, for instance, there was a small, extremely early lesion of the left upper lobe indicated in the roentgenogram by a patch of "soft" beaded trunks about 2 cm. above the center of the interlobar fissure. The fissure was visible as a transverse line with a marked upward curve at the center. After the patient had had two months' rest, roentgenographic examination showed almost normal parenchyma and a straight interlobar line. It was evident that the tissues had collapsed partially when actively infected and had reexpanded during healing. Bronchial obstruction was certainly not responsible for the collapse, since the infected portion was air containing, and the collapse disappeared much too quickly for it to have been due to scarring. The most likely cause was increased elastic tension and resistance to inflation on account of interstitial septal fluids and cells. This selective collapse is evidently an agent of rest for the inflamed parenchyma, as well as of compression.

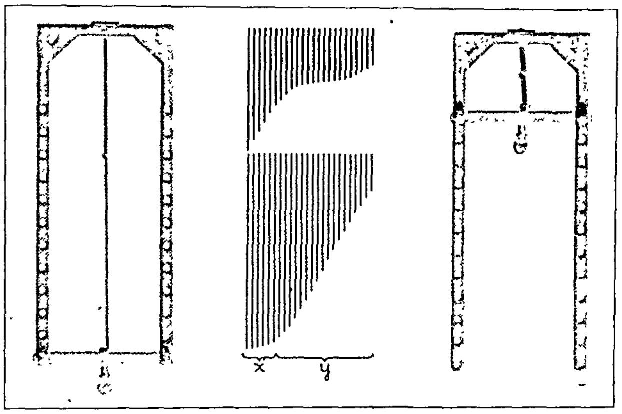

Fig. 5.—Model which demonstrates the principle of differential pulmonary elasticity probably responsible for selective collapse after phrenicotomy.

Selective collapse is not seen in every case of tuberculosis treated by pneumothorax, because it is prevented by adhesions, or because the lung is relaxed too much, or because the inflammation is too widespread. So, too, and probably for the same reasons, the phenomenon is not seen regularly after therapeutic paralysis of the diaphragm. It is detectable even less frequently after phrenicotomy than after pneumothorax, likely because pulmonary landmarks are seldom available in the first case to delineate the boundaries of the normal and diseased tissues, whereas they are always furnished in the second by the pleural surfaces. Selective collapse after phrenicotomy as extensive and evident as that seen in the two patients described here is unusual in my experience, while usually healing of the lesion regardless of its location in relation to the diaphragm affords the only evidence of the selective effect.

SUMMARY

The occurrence of selective collapse of the lung in pulmonary tuberculosis after phrenicotomy has been referred to and illustrated with cases. It has been compared in principle to selective collapse after pneumothorax. For both operations, differentiation is made between the deflation of the diseased tissues which occurs immediately and is probably due to increased elastic tone of the lung, and that which occurs gradually and is due to formation and contraction of scar tissue. The increased elastic tension of the lung, in the first type, is believed to be due largely to thickening of the pulmonary septums and membranes from vascular congestion and interstitial deposit of inflammatory fluids and cells.

LIPODYSTROPHY

ATROPHY AND TUMEFACTION OF SUBCUTANEOUS TISSUE DUE TO INSULIN INJECTIONS

ALBERT H. ROWE, M.D.
AND
OLIN H. GARRISON, M.D.
OAKLAND, CALIF.

Atrophy of the subcutaneous tissues producing depressed areas on the skin as a result of insulin injections was first reported in 1926 by Barborka.[1] He noted two instances of such atrophy and recommended massage of the tissue after insulin therapy and a variation of the site of injection. He found no evidence of inflammation and no muscular weakness or evidence of nerve injury. In the same year, Depisch[2] recorded five cases of atrophy due to insulin and stated that the onset might vary from a few months up to two years after the start of the treatment. He noted some impairment in sensations over the affected area. In 1927, Mentzer and DuBray[3] reported an instance of this condition. Sections of the area did not indicate any inflammatory changes. Davidson,[4] in the same year, observed atrophy in a woman four months after the beginning of insulin therapy.

In 1928, the following articles were published: Rabinovitch[5] observed atrophy in eight patients. He found no lipase in insulin. Chapman[6] reported the disappearance of atrophy two and one-half years after the site of the insulin injection had been changed. Lawrence[7] found lymphocytic infiltration with some plasma cells and eosinophils in injected nonatrophic areas. He felt that the method of preservation of the insulin or the sterilization of the needle were not at fault but that damage to the delicate protoplasmic envelop of the fat cells released fat globules, which in turn stimulated histiocytes, which assumed lipophagic activity. Such lipophagic cells were reported by Gilchrist and Ketron[8] in 1916 from another type of injection. Carmichael and Graham [9] recorded three instances of atrophy and suggested that it might be due to lipase in the insulin. Joslin [10] recorded three cases of subcutaneous atrophy. One of the patients complained of pain in the depressed area.

In 1929, Fischer [11] studied twenty-four children who had received insulin for more than six months. Atrophy was present in eight patients and slight evidences of this trouble were found in eight others. In the same year, McCormick and Moorhead [12] observed two instances of atrophy. In one woman it had appeared after six injections.

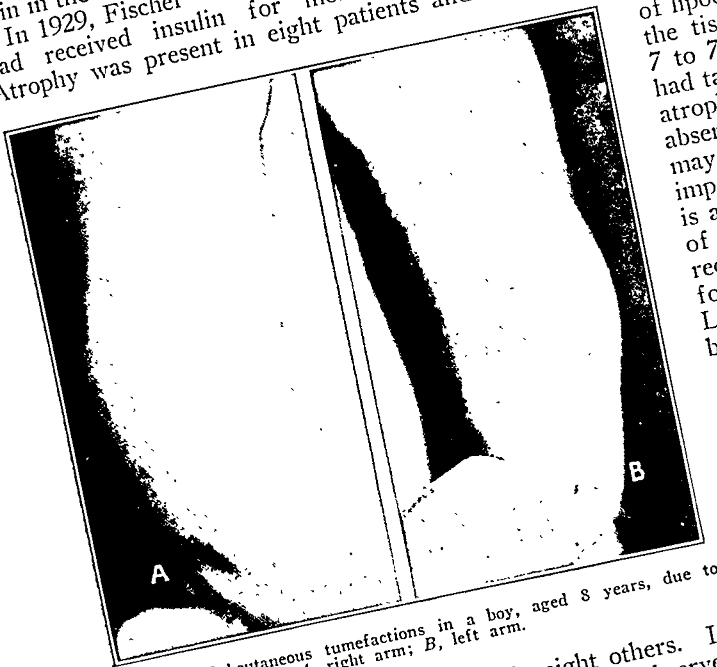

Fig. 1.—Subcutaneous tumefactions in a boy, aged 8 years, due to injections of insulin: *A*, right arm; *B*, left arm.

In 1930, Reed, Anderson and Mendel [13] found no lipodystrophy in the tissues of rats after injections of insulin or salt solution. Depisch [14] again discussed the subject and stated that about 10 per cent of all patients, especially women, who continue insulin up to two years develop atrophy as a result of traumatic and chemical effect from the insulin itself. Woodhouse,[15] in 1930, reported postmortem studies of an atrophic area in a patient. No evidence of inflammation was found. Nichols [16] recorded large areas of atrophy beyond the immediate site of infection in line of lymphatic drainage. In two years, regeneration of the fat had occurred. He noted that females and children were especially susceptible. Priesel and Wagner [17] suggested that tricresol might be responsible for the atrophy. Boller [18] reported eight instances of atrophy and stated that Falta had seen six cases in one year in his practice. Stransky [19] reported one instance of lipodystrophy and suggested the addition of procaine hydrochloride to the insulin to reduce the distress of the injection. In 1930, Eeg-Olofsson [20] noted atrophy in a woman ten months after beginning insulin therapy. Microscopically, fatty atrophy and small areas of round cell infiltration similar to that occurring after any hypodermic injection were found.

During the last nine years, since his first use of insulin, one of us, (A. H. R.) observed two instances of lipodystrophy. Recently we have carefully examined the tissues of fifty patients whose ages varied from 7 to 79, with an average age of 40.6 years, and who had taken insulin for an average of one year. Definite atrophy was observed in two additional cases. The absence of atrophic reaction in more of our patients may be due to the emphasis we have always laid on the importance of the variation in the site of injection. It is also interesting to report that definite fatty atrophy of subcutaneous tissue occurred in one patient who had received pollen therapy in the same area once a week for ten months. This corroborates the opinion of Lawrence that mechanical injury of the fatty cells may be the true cause of the atrophy.

SUBCUTANEOUS TUMEFACTION

Recently an increase in the subcutaneous tissue in the outer aspect of each arm has been observed in one of our patients, a lad of 8 years, who was first seen by us at the age of 16 months in precoma. Insulin has been given ever since and in spite of our warning to give it in varying areas the injections had alternately been given in the same areas of the arms. During the last year the swellings had appeared and had gradually increased so that when seen five months ago they were soft and nonpainful and semifluctuating. No changes in sensation were present. Since injections in these areas have been stopped, the swellings have diminished to about half their size. The insulin was being absorbed satisfactorily from the swollen areas, since no decrease in insulin has been possible since the change. In fact, the mother thinks that the swollen areas absorbed the insulin faster than do the tissues in the legs. The boy is well and vigorous, weighs 64 pounds (29 Kg.) and measures 50½ inches (128 cm.) in height, which is 1 inch below the normal for his age.

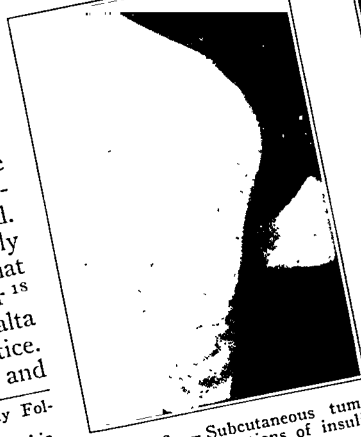

Fig. 2. — Subcutaneous tumefaction from injections of insulin in a woman, aged 50.

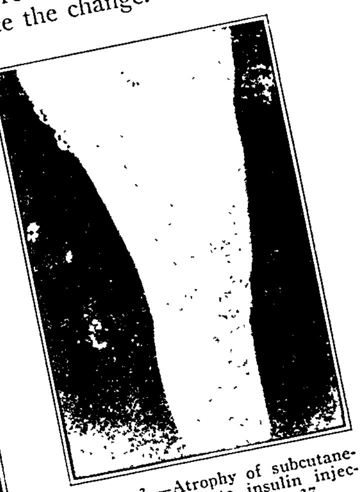

Fig. 3.—Atrophy of subcutaneous tissue due to insulin injections in a woman, aged 37.

In the examination of the fifty patients already referred to in this paper, three other patients with tumefactions due to repeated injections of insulin were found. A half lemon sized swelling in the outer surface of both arms occurred in a girl, aged 19 years, who had taken 70 units of insulin daily for seven years. These swellings had appeared during the last six months. Another girl, aged 12 years, had a moderate swelling on the arm, which disappeared in two months after the site of injection was changed. She has taken 32 units of insulin for five years and noticed the swelling one year ago. The other tumefaction occurred in a woman, aged 50, on the outer aspect of the right thigh. She had used this area for six months and had taken 16 units of insulin for one year. All these swellings were soft, nonpainful and noninflammatory.

We have found one other record of such tumefaction resulting from insulin therapy. Eeg-Olofsson noted it in a 16 year old girl who had taken 12 units twice daily in the outer surfaces of the thighs for one and one-half years. After this, increasing swellings occurred. "Two symmetrical tumors, about the size of fists," were present. They were nonpainful, soft and pseudofluctuating. The skin was firmly attached but the swellings were movable over the underlying muscles. Section of the tumor showed a chronic inflammatory reaction consisting of round cell infiltration, increased connective tissue and hemosiderosis. No definite increase in fatty tissue was noted. Strong fibrous strands extended from the skin into the subcutaneous fat. In one year after cessation of injections in the swollen areas, the tumefactions had practically disappeared.

THE TREATMENT OF OBSTINATE CHOREA WITH NIRVANOL

WITH NOTES ON ITS MODE OF ACTION

T. DUCKETT JONES, M.D.
AND
JOHN LESH JACOBS, M.D.
BOSTON

During the last fifteen years the capacity of nirvanol to produce a syndrome known as "nirvanol sickness" has been widely utilized in German clinics in the treatment of violent choreas.[1] Nirvanol is phenyl-ethyl-hydantoin, an hypnotic resembling phenobarbital in its pharmacologic action, but with a five instead of a six membered ring nucleus. "Nirvanol sickness" consists of fever, rash and eosinophilia, coming on sharply in a high percentage of persons treated, usually from six to twelve days after the first administration of the drug. It has been generally observed that following the appearance of this syndrome the course of the disease is shortened.

Recently similar reports have come from England.[2] Poynton and Schlesinger[3] have even observed the disappearance of persistent rheumatic nodules, accompanied by a lowering of temperature and quieting of the pulse rate, in four patients with "subacute rheumatism" who were given the usual course of nirvanol treatment. Three patients in the same series were not improved.

Some authors[4] consider "nirvanol sickness" to be caused by a specific idiosyncratic reaction to the drug; others[5] believe it due to a cumulative toxic phenomenon. Instances of heavy overdosage without harmful effect are on record;[6] on the other hand, several deaths, possibly but not certainly due to the drug, have been reported.[7]

This investigation was begun with the hope of obtaining information as to the value of the use of nirvanol in obstinate chorea and concerning the mechanism of its action. Two children and one young adult with persistent chorea were selected for the treatment. They had not been benefited by other usual forms of therapy, as described hereafter. Each of these patients was given approximately 0.0063 Gm. of nirvanol per pound a day in hot tea. This was estimated to be an average dose from Lesigang's series of 106 cases, the largest found in the literature. Owing to serious complications following the administration of nirvanol in one patient, the investigation was not followed further than an examination of the first series of three cases. Abbreviated case histories follow.

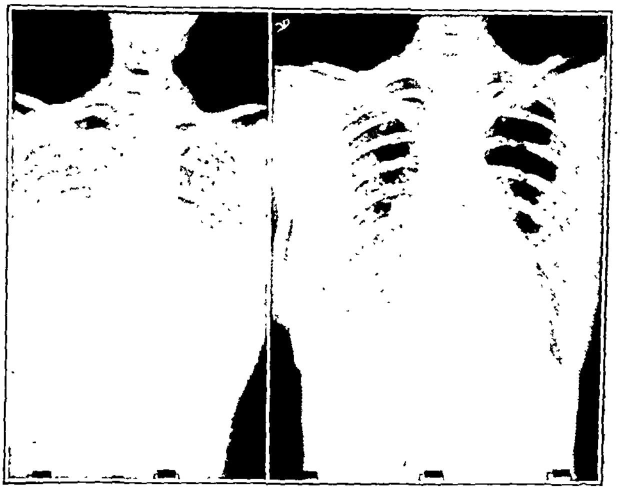

Fig. 1.—Portable x-ray chest plates, showing changes occurring during "nirvanol sickness" and after process had cleared.

REPORT OF CASES

Case 1.—M. F., a girl, aged 12 years, was well until May, 1928, when she had definite chorea for the first time, lasting two months. In January, 1930, she became nervous, soon followed by a recurrence of chorea. There was marked athetosis, speech difficulties and temperamental changes. She was hospitalized from February 24 to March 7, with definite improvement in the chorea. On one occasion slight, transitory polyarthritis appeared. She was admitted to the House of the Good Samaritan, March 7, with definite but mild chorea. There

was no demonstrable evidence of heart disease, and she was well developed and nourished, weighing 61 pounds (27.7 Kg.).

From March 8 through April 27, 15 minims (0.9 cc.) of tincture of stramonium three times a day was given without any change in the chorea. The patient weighed 63¾ pounds (28.9 Kg.) on the latter date.

On April 28, 29 and 30 she received 0.4 Gm. of nirvanol daily. She was awake during the day but slept heavily at night. The drug had no effect on the chorea.

May 1, 2, 3 and 4, she received 0.2 Gm. of nirvanol daily. The chorea, if anything, was more active.

May 5, she developed a scarlatinal rash over the forearms, body and legs. Nirvanol was not given. There was no fever. The chorea was slightly more active.

May 6, the patient received 0.2 Gm. of nirvanol. The rash was fading. There was no fever. The chorea became slightly less active.

The rash faded within several days. May 10, there was no temperature reaction; the weight was 63½ pounds (28.8 Kg.). Figure 2 shows blood changes occurring as a result of nirvanol treatment.

June 5, 1931, the patient was still hospitalized for mildly active chorea, which was not demonstrably affected by the nirvanol therapy. There has been a gradual increase in weight to 90½ pounds (41 Kg.). There is no clinically demonstrable heart disease. Two subsequent courses of stramonium have not affected the chorea.

CASE 2.—S. L., a girl, aged 9 years, was well until March, 1929, when two weeks after complaining of unsteadiness in walking she developed violent chorea and could neither stand nor speak. She was hospitalized from April 15 to June 1, and from June 1 until July 24 she was in a foster home. On admission to the House of the Good Samaritan, July 24, there were mild to moderate choreiform movements with a definite speech defect. There had been a gradual improvement in the chorea from the time of first hospitalization, with a loss of 15 pounds (6.8 Kg.) in the last four months. No demonstrable heart disease was found. During the first two months at the House of the Good Samaritan there were frequent rises in temperature to between 100 and 101 F. (rectal). The white blood count was consistently above 10,000.

From September 6 to October 1, 8 minims (0.5 cc.) of tincture of stramonium was given four times a day. It had no effect on the chorea.

From November 24 to December 17, the dosage was repeated. It had no effect on the choreiform movements but the speech defect improved slightly. There was no longer any fever and the white blood count remained consistently below 10,000.

From June 14, 1929, to April 27, 1930, 15 minims (0.9 cc.) of stramonium was given three times a day. It had no effect on the chorea, which continued definite, though mild. The weight was 68 pounds (31 Kg.).

April 28, 29 and 30, the patient received 0.38 Gm. of nirvanol daily. She slept heavily but was not drowsy during the day. There was no change in the chorea.

From May 1 to 6, she received 0.2 Gm. of nirvanol daily. The chorea was possibly a little more active. The temperature was 101 F. (rectal) the afternoon of May 6.

May 7, a definite maculopapular rash appeared on the arms, face, legs and buttocks in the form of pink areolas with light colored centers, the sizes varying from 1 or 2 mm. to 10 mm. in diameter. The rash was more noticeable in the pressure areas. There was no fever: no change took place in the chorea.

May 8, more areas of rash appeared but the majority were fading. There was no fever.

May 16, there was no further fever. The rash disappeared completely in about four days. The chorea remained unchanged. Figure 2 shows blood changes occurring as a result of nirvanol treatment.

May 15, 1931, the patient was discharged from the House of the Good Samaritan to the Contagious Hospital because of measles. During the past year there has been no change in the mildly active chorea. The weight has increased to 74 pounds (33.6 Kg.). There is no evidence of heart disease.

CASE 3.—F. L., a girl, aged 17 years, was well until January, 1927, when she had rheumatic fever. Three months later, heart disease was diagnosed for the first time by the school physician. In May, 1929, there was a recurrence of rheumatic fever with migrating polyarthritis. The patient was hospitalized for six weeks. July 1, polyarthritis returned and there was also stabbing precordial pain. She was in bed for three weeks prior to admission to the House of the Good Samaritan, July 23. She lost 16 pounds (7.3 Kg.) in three or four months. On admission the patient was rather pale, tall and poorly nourished. There were occasional mild choreiform movements of the hands. Her weight was 94¾ pounds (42.9 Kg.). The temperature occasionally rose to 100.5 F. (mouth) during the first month. Definite swelling and tenderness developed in the right metacarpophalangeal joint just after admission. There was slight cardiac enlargement and apical systolic and diastolic murmurs of mitral disease. The chorea became considerably worse several days after admission; the medication and course of the chorea may be summarized as follows:

From July 27 to August 2, ½ grain (0.03 Gm.) of phenobarbital was given three times a day.

From August 3 to August 10, 1 grain (0.06 Gm.) of phenobarbital was given three times a day. It had no effect on the chorea.

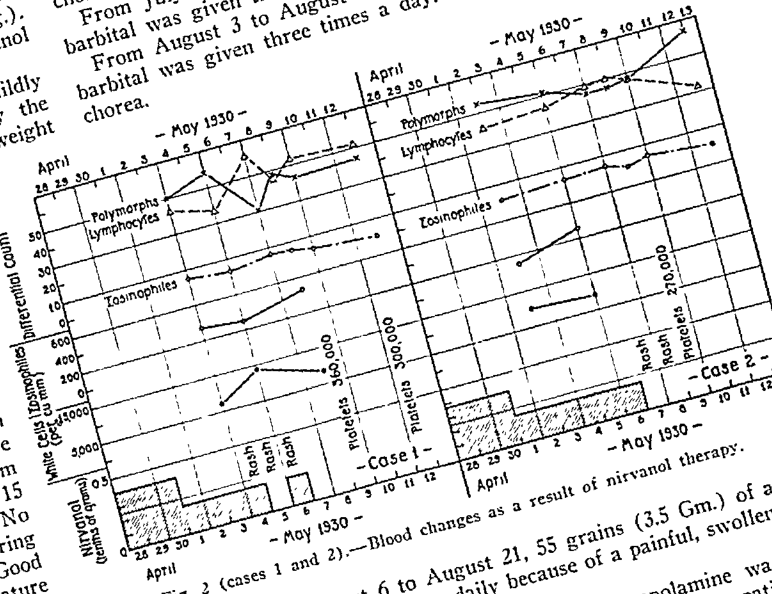

Fig. 2 (cases 1 and 2).—Blood changes as a result of nirvanol therapy.

From August 6 to August 21, 55 grains (3.5 Gm.) of acetylsalicylic acid was given daily because of a painful, swollen wrist and elbow.

August 8, 1/100 grain (0.6 mg.) of scopolamine was given subcutaneously. The chorea became violent. The patient was isolated.

From August 9 to August 21, 1 drachm (4 cc.) of paraldehyde was given four times a day. The chorea continued to be violent. There was no effect from the paraldehyde. Warm baths (not continuously) were ineffective.

From August 22 to September 1, 8 minims (0.5 cc.) of tincture of stramonium was given four times a day.

From September 1 to September 21, 10 minims (0.6 cc.) of tincture of stramonium was given four times a day.

Two or three days after the stramonium medication was begun the choreiform movements became less violent.

From November 1 to November 25, 8 minims of tincture of stramonium was again given four times a day.

There was a gradual subsidence of chorea to moderate activity, and the patient returned to the ward, Jan. 12, 1930.

From January 12 to March 7, 15 minims of tincture of stramonium was given three times a day. There was a gradual subsidence of chorea to mild activity. There still were definite purposeless movements. A small spontaneous nosebleed occurred, March 7. The patient was allowed out of bed, up to two hours daily, from March 24 to April 11, but the chorea became moderately active and she had to be returned to bed.

From March 6 to April 27, 15 minims of tincture of stramonium was given three times a day. The chorea became moderately active. The patient's weight, April 27, was 93 pounds (42.2 Kg.).

April 28, 29 and 30, she received 0.55 Gm. of nirvanol daily. She became very drowsy but it had no real effect on the choreiform movements.

May 1 and 2, she received 0.3 Gm. of nirvanol daily. There was a severe nosebleed, May 2. The chorea became slightly more active, but the patient was stuporous most of the time. The temperature rose to 102 F. (rectal).

May 3, a very fine macular pink rash appeared on the dorsum of the feet and ankles. She continued to be drowsy. The temperature rose to 103 F. (rectal). No platelets were found in the blood smear. The chorea became somewhat more active.

May 4, an extensive scarlatiniform rash appeared over the entire body. The temperature rose to 100 F. (rectal). The chorea remained unchanged.

May 5, the rash was present but fading. The patient was still drowsy. The chorea became less active. The temperature rose to 100.2 F. (rectal). No platelets were found in the blood smear.

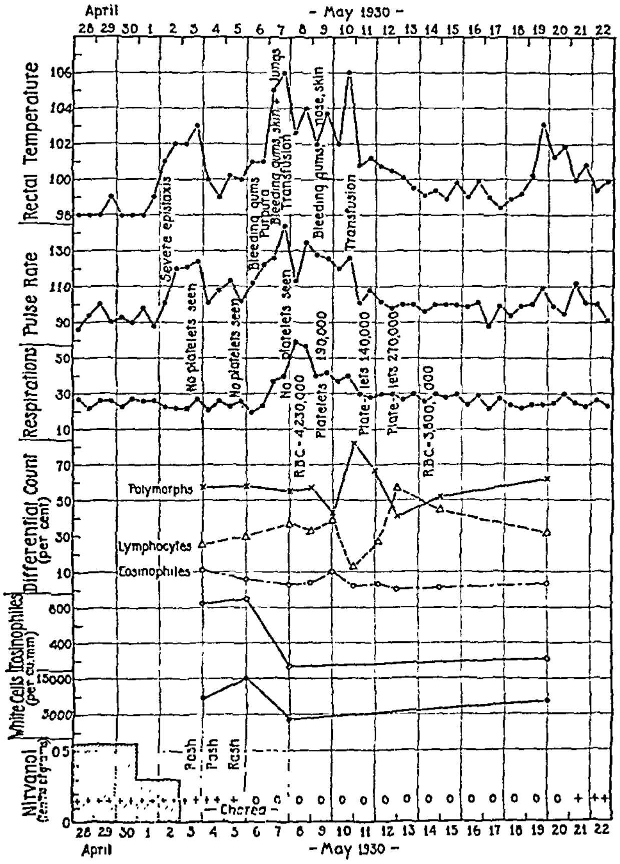

Fig. 3 (case 3).—Severe reaction to nirvanol therapy.

May 6, a mild but persistent bleeding began from the gums. Following venipuncture numerous and extensive hemorrhagic areas appeared below the tourniquet. She was bleeding into the skin and subcutaneous tissues. The patient looked ill. There was no chorea. She was stuporous. The temperature rose to 101 F. (rectal).

May 7, at 6 a. m. the patient suddenly became weak and cyanotic. She had a dry, irritating cough, and respirations were up to 40. The temperature was 105 F. (rectal), pulse 144. The bleeding from the gums continued. Numerous extensive, coarse, moist râles were heard throughout both lungs. There was an increase in the purpuric areas. Petechiae appeared over the arms, trunk and legs. No platelets were seen in the blood smear. Bleeding time was sixty minutes. Direct transfusion of 400 cc. of blood was done. The temperature rose to 106 F. (rectal) after transfusion. Rapid respirations and mild cyanosis continued. There was an irritating, nonproductive cough. There was no chorea. The patient was drowsy but alert when awakened. Her condition was critical.

May 8, she was more awake and alert. There was no fresh bleeding; the cough continued; cyanosis was less. There were numerous râles throughout the lungs as before. The temperature rose to 104 F. (rectal). No platelets were seen in the blood smear. Reticulocytes were 28 per cent; red blood cells, 4,230,000. The benzidine test on the stool was frankly positive. Portable x-ray films showed a few small, mottled areas in the first interspace on the left, and entire right chest dull, with several rounded areas of increased density within the lung fields. These were thought to be hemorrhagic areas occurring probably at the time of the collapse of the day before.

May 9, the patient was better most of the day with respirations down to 30 and the lungs much clearer. She was brighter. There was occasional bleeding from the gums. There was mild nosebleed and several small, fresh showers of petechiae. Platelets numbered 190,000. Bleeding time was six minutes; coagulation time, six minutes. About 10 p. m. she began to bleed persistently again from the gums and nose.

May 10, bleeding was profuse until 4 a. m., and chiefly from the nose, pharynx, palate and gums. One-eighth grain (8 mg.) of morphine, subcutaneously, resulted in some rest. Respirations were 30. The temperature rose to 106 F. (rectal). Direct transfusion of 450 cc. of blood at 11:30 a. m. had no reaction. Roentgen examination showed a slight amount of fluid in both chests and changes suggesting general edema of the lung.

May 11, there was no further bleeding. The patient was more comfortable, and awake most of time. The temperature rose to 101 F. (rectal). The fluid intake and output remained good throughout. The benzidine test was still positive on the stool. *There was no further chorea.*

May 12, there was no further bleeding. Platelets were 270,000. Bleeding time was three minutes. May 14, she was considerably better. Red blood cells numbered 3,900,000; platelets, 270,000; bleeding time was four minutes.

May 20, after a week of normal temperature without further bleeding, the temperature the night before rose to 104 F. (rectal), and this night 102 (rectal). Respirations were under 30. The cervical glands were considerably enlarged.

May 22, roentgen examination showed the lungs practically clear, the peculiar process having disappeared (fig. 1). Mild chorea had returned.

June 1, the chorea had returned to a moderately active degree, as active as prior to the nirvanol therapy. The weight now was 85 pounds (38.6 Kg.), an 8 pound (3.6 Kg.) loss. There were rare, slight nosebleeds. (In figure 3 one may find the diagrammatic representation of the important events occurring as the result of the nirvanol therapy. Blood changes and temperature charts are especially interesting.)

June 5, 1931: The patient has been hospitalized continuously for mild to moderately active chorea, which has varied but little since the nirvanol therapy. The weight is 95 pounds (43 Kg.). On two occasions she has been allowed up but returned to bed because of increased chorea. There have been nosebleeds and on one occasion erythema multiforme. On examination there is moderate cardiac enlargement and evidence of mitral and aortic disease. The general condition is good.

CLINICAL COMMENT

Histories of three obstinate cases of chorea are given, with emphasis on their response to nirvanol therapy. In each of the three cases, "nirvanol sickness" was produced. The dosage was halved after three days and discontinued on the first appearance of rash. A definite rash occurred in each case as described in the case reports; on the sixth day in case 3, and on the eighth and ninth days respectively in cases 1 and 2. Case 1 at no time showed a temperature reaction, and in case 2 there was a single rise to 101 F. (rectal), sixteen hours prior to the appearance of the rash. Definite eosinophilia occurred in all cases, with an inversion of the neutrophilic and lymphocytic ratios, which is shown in figure 2. There was a definite increase in the total eosinophils, as shown in the same chart. The charts are strikingly similar to those presented by Poynton and Schlesinger. Case 3 failed to show the usual variation in neutrophilic and lymphocytic elements until quite late, probably because of the complication of hemorrhage.

The most interesting phase of this report is concerned with the unusual reaction of case 3 to nirvanol therapy. A definite rash appeared on the sixth day, preceded by a temperature rise to 102 F. (rectal). On the ninth day after therapy was begun, bleeding occurred, first from the gums, then into the skin and subcutaneously. Blood platelets disappeared from the smear. There was a conspicuous prolongation of bleeding time with coagulation time unchanged. A sudden pulmonary episode occurred on the ninth day, possibly best explained as bleeding into the lung tissue (fig. 1). Each of two transfusions was followed by definite improvement. The blood picture resembled bone marrow suppression, as produced with nirvanol in rabbit studies by Leichtentritt and Lengsfeld,[5] and that seen in human beings, in benzene and arsphenamine poisoning. In addition, there was a secondary reaction, three weeks after therapy was begun, consisting in a rise in fever of two days' duration. The first reaction with its unusual pulmonary complication was nearly a fatal issue and shows clearly that the drug is one not to be used indiscriminately. Pilz [8] reported a somewhat similar case in 1927. The resemblance of these symptoms to the lung picture in barbital (veronal) poisoning (Willcox [9]) suggests a common toxic mechanism.

In each case the nirvanol caused sound sleeping, and in case 3 drowsiness. If anything, the chorea was slightly increased near the onset of "nirvanol sickness." In case 3 it completely disappeared for about two weeks following the reaction. All three patients have maintained their chorea unaltered, and one year following the use of the drug they continue to show mild choreiform movements.

COMMENT ON METHOD OF ACTION OF NIRVANOL

The very high incidence of skin rashes following the administration of nirvanol suggests the operation of a specific idiosyncrasy. Nirvanol produces an irritant reaction in the normal human skin, which makes any estimation of specific skin hypersensitiveness extremely difficult and necessitates careful controls. Two related drugs, phenobarbital and acetyl-nirvanol, which resemble nirvanol in their action in the normal human skin, were used for comparison. In the course of a number of intradermal tests on each patient, done with varying dilutions of the materials, before, during and subsequent to the appearance of their skin rashes, no evidence was obtained of a specific idiosyncratic reaction to nirvanol, either immediate or delayed.

In a recent paper Biberstein [10] asserted that he transferred atopic reagins to mercury and other chemicals from idiosyncratic (skin-reactive) patients by means of the Prausnitz-Küstner technic. Transfers by this technic from our three patients during and subsequent to the appearance of their skin rashes were negative. Since nirvanol does not cause a nonspecific contraction of the guinea-pig uterus, 6 cc. of blood serum taken from patient 3, May 14, was injected into a female guinea-pig for the purpose of testing for passive sensitization by the Dale uterus technic. On the next day the uterus did not react to nirvanol in the Dale apparatus.

Three guinea-pigs and three rabbits were given a course of nirvanol in doses corresponding by weight to those used in human therapy. None of these animals became skin-sensitive to nirvanol either during or after the injections, nor did any animal exhibit an abnormal rise or fall in temperature. After an incubation period of nineteen days following the last injection, the guinea-pigs were injected intraperitoneally with 30 mg. of the drug. No anaphylactic symptoms were observed. Since Leichtentritt and Lengsfeld [5] observed a deleterious effect on the bone marrow of rabbits injected with large doses of nirvanol, such evidence as is available from animal experiments favors a toxic explanation of the drug's action. In view of the difficulty with which the barbital series is excreted, and the resemblance of symptoms of severe "nirvanol sickness" to those seen in barbital poisoning,[9] it would seem to be advisable for practical purposes to consider that the doses being used at present in the treatment of chorea produce toxic symptoms which may lead to dangerous complications.

SUMMARY

1. Treatment with a course of nirvanol produced no permanent benefit in three obstinate cases of chorea.
2. One of the patients suffered a dangerous reaction to the drug. The details are reported.
3. Tests for the presence of a specific hypersensitiveness to nirvanol were consistently negative.

Clinical Notes, Suggestions and New Instruments

TOXIC CIRRHOSIS OF THE LIVER DUE TO CINCHOPHEN COMPOUNDS: REPORT OF THREE FATAL CASES

Clifford R. Weis, M.D., Dayton, Ohio

Since the introduction of cinchophen (phenyl-quinoline-carboxylic acid) in 1908 by Nicolaier and Dohrn,[1] its use has become widespread as an analgesic, particularly in arthritis. The fact that it may be purchased without a physician's prescription and is usually the chief constituent of many so-called rheumatism cures has added to its increasing use.

That the drug or its preparations may cause toxic symptoms was observed by von Muller,[2] Herrick [3] and Phillips.[4] In 1922, Schroeder [5] first drew attention to the toxic properties of the drug variously known as phenylcinchoninic acid, cinchophen, quinophan, atophan, agotan and phenoquin. He reported seventeen cases, chiefly of mild poisoning, consisting of headache, gastro-intestinal disturbances, and transient jaundice. Following Langdon-Brown's [6] communication in 1926, a dozen fatalities were reported by Evans,[7] Glover,[8] Willcox [9] and Wells.[10]

In 1925, Cabot [11] reported the first death, from acute yellow atrophy of the liver, of a patient who had taken "Weldona" tablets. Rabinowitz,[12] in 1930, collected forty-one cases in the literature and added nine additional cases. There were twenty-five deaths in this series of cases with twenty autopsies which

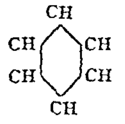
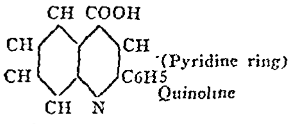
confirmed the diagnosis of acute yellow atrophy. Parsons and Harding,[13] in 1931, reported four fatal cases and classified the symptoms roughly into four groups: (1) cutaneous manifestations, such as pruritus, angioneurotic edema, urticaria, and macular and papular eruptions, exemplified by Phillips[4] in 1913; (2) anaphylactoid reactions characterized by neurocirculatory disturbances associated with rapid pulse and lowered blood pressure following the ingestion of a single dose of cinchophen, as mentioned by Scully[14] in 1924; (3) gastro-intestinal disturbances including simple aphthous ulcers in the mouth, pyrosis, nausea, vomiting, and diarrhea, reported by Schroeder[5] in 1922, and (4) liver involvement as indicated by the appearance of jaundice, first noted by Worster-Drought[15] in 1923. Recently Beaver and Robertson[16] reviewed five fatal cases at the Mayo Clinic and suggested a specific pathology for cinchophen poisoning of the liver, which "is essentially dissimilar to the ordinary Laënnac or portal variety."

Chemically, cinchophen is 2-phenyl-quinoline-4-carboxylic acid.



Benzene



Cinchophen

Rotter[17] states that it is excreted in the urine as 2-ortho-hydroxyl-phenyl-quinoline-4-carboxylic acid, an oxidation product. According to Willcox[9] the toxic action of the drug is due to the quinoline nucleus, consisting of the benzene and the pyridine rings, which yield the toxic ring of free benzene. Willcox says: "It is well known that jaundice occurs after the administration of the arsenobenzene compounds of arsenic, and the occurrence of jaundice is no doubt due to the combination of the arsenic with a benzene nucleus." The quinoline nucleus resembles that of benzene in that its presence may be associated with toxic action on the liver.

REPORT OF CASES

Case 1.—G. B., a man, aged 26, entered St. Elizabeth Hospital, March 8, 1930, in delirium. Three weeks before entrance the father of the patient noticed jaundice of the sclerae and called the son's attention to it. During the next week the jaundice deepened, nausea and vomiting ensued, and he became lethargic. The urine was dark, and, during the three days before admission to the hospital, delirium was present. From the father of the patient it was learned that his son had been taking eight "Atophan" tablets daily for the relief of "rheumatism," which had followed an attack of tonsillitis three months before. No history of indigestion could be obtained.

On physical examination the patient presented a picture of marked icterus and was in mumbling delirium. The temperature was 98.0 F., pulse 96 and respiration 24. The blood pressure was 110 systolic and 84 diastolic. The heart was normal. The bases of both lungs were dull and the breath sounds absent. The area of liver dulness was markedly decreased. The superficial reflexes were present. Edema of the ankles was present, as mentioned by Sutton.[18]

The laboratory data showed the urine to contain bile, a few finely granular casts and a few red blood cells. The erythrocytes numbered 4,500,000, the leukocytes 12,500 with 80 per cent polymorphonuclears. The concentration of hemoglobin was 90 per cent (Dare). The blood and spinal Wassermann tests were negative. The blood platelets numbered 110,000 per cubic millimeter. The coagulation time was seven minutes. The icterus index was 40. The retention of bromsulphalein in sixty minutes was 60 per cent. The nonprotein nitrogen was 46 mg. in 100 cc. of blood.

Dextrose and insulin were given. March 12, 1930, the coma deepened; the temperature rose to 102.3 F. and the pulse to 120. That evening the respiratory rate rose to 36, the chest was full of bubbling râles, and the temperature was 104.3 F. just before the patient died.

The autopsy showed that the patient had been well nourished, with evidence of recent loss of weight. The skin approached a bronze color. The heart was normal. The lungs showed red hepatization of the lower lobes. The liver weighed 680 Gm. and showed myriads of fine yellow nodules studding the surface among a reddish-brown tissue. Microscopically, the liver tissue showed icterus, *necrosis of the parenchyma and cirrhosis* of the liver with compression of the lobules. Marked regeneration of the bile ducts was evident, with fatty infiltration around the lobule periphery.

There was no evidence that this young man had any hepatic disease. He had taken about 60 grains (4 Gm.) of "Atophan" daily for three months for relief of pain. The history and the clinical course, with the autopsy, leave little doubt that cinchophen was the toxic agent.

Case 2.—J. P., a man, aged 65, a painter, entered St. Elizabeth Hospital, Jan. 1, 1931, with the complaint of arthritis and jaundice. For four months he had been taking "Atophan," eight tablets daily, for relief of pain. No history of indigestion could be obtained. Two and a half weeks before admission he was obliged to quit work because of progressive weakness, loss of appetite, increasing drowsiness and nausea. Jaundice developed, and in a few days he began to vomit. He noticed that the urine was dark and that it "burnt." He was given "liver tablets" by his physician without relief and a week before admission began to have periods of transient delirium. The urine became diminished in amount, he was unable to take nourishment, incontinence of urine and feces developed, the delirium increased, and the skin became bronzed. The tongue became dry, the lips cracked and he was admitted to the hospital in delirium and had to be mechanically restrained.

The patient was poorly nourished. The temperature was 100.1 F., pulse 84 and respiration 22. The heart and lungs were normal. The blood pressure was 86 systolic and 60 diastolic. The area of liver dulness was greatly diminished. No lead line was seen on the gums. Edema of the hands and feet was observed. The hands showed marked hypertrophic arthritis.

The laboratory data revealed that the urine contained a trace of albumin, bile, and a few finely granular casts. The concentration of hemoglobin was 85 per cent (Dare). The erythrocytes numbered 4,100,000 and the leukocytes 16,000, with 92 per cent polymorphonuclears. No stippling was seen. The blood and spinal Wassermann tests were negative. The nonprotein nitrogen was 62 mg. per hundred cubic centimeters of blood and the creatinine 2.1 mg. The icterus index was 54. The retention of bromsulphalein in sixty minutes was 85 per cent.

Dextrose and insulin were given. The general condition remained unchanged during the next four days. On the fifth day the coma deepened, the temperature rose to 104.4 F., the pulse to 136, a profuse perspiration covered the body, and death followed that evening.

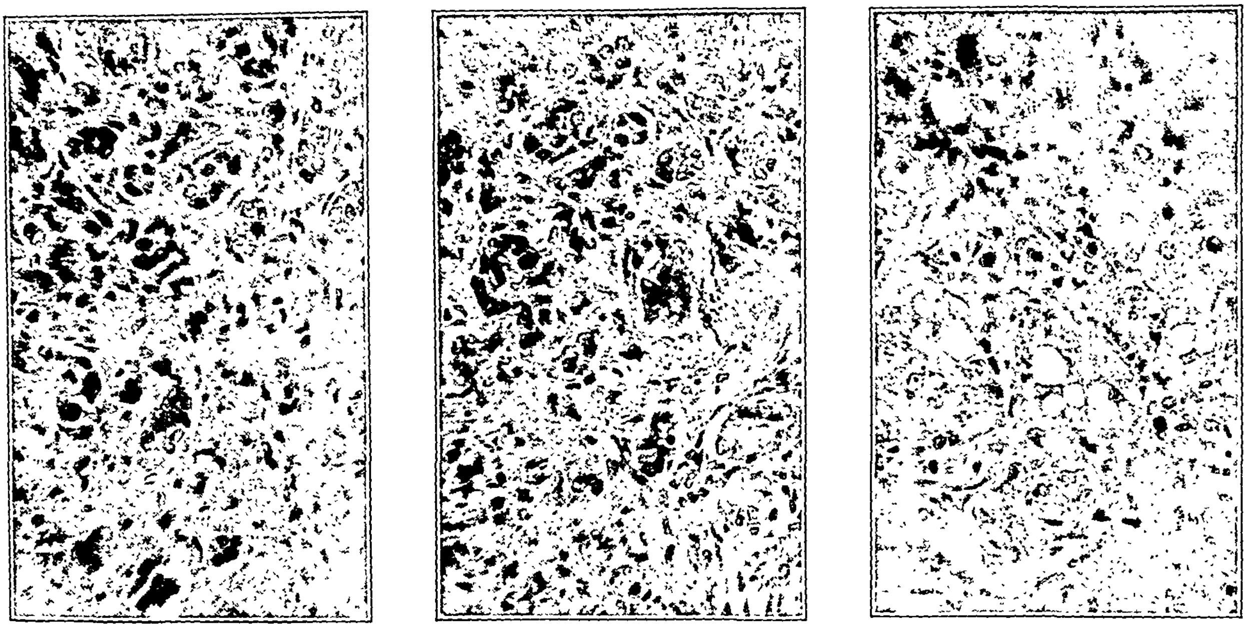
The autopsy revealed that the heart and lungs were normal. The liver was roughly nodular, similar to that in case 1 grossly. The gallbladder, ducts and pancreas were normal. The suprarenals were normal. The kidneys showed slight diffuse nephritis. On section, the liver showed icterus, degenerative necrosis of the parenchyma, increase in connective tissue and compression of regenerated liver lobules into cirrhotic formation. Completely intact lobules were not found.

This is a case of acute toxic cirrhosis in an elderly man without evidence of previous hepatic disease. For fourteen weeks he had taken 60 grains of "Atophan" daily to relieve pain. No other etiologic agent could be demonstrated.

Case 3.—Mrs. E. L., aged 64, entered St. Elizabeth Hospital, Nov. 15, 1931, in coma. Her husband stated that she had been perfectly well except for an attack of "arthritis" in December, 1930, for which she had various treatments. In July, 1931, the pain became worse and she began to take four "Farastan" tablets (Mono-iodo-cinchophen) daily with relief of the pain. She felt well until eleven days before admission, when icterus was noticed in the sclerae. Within twenty-four hours the body was deeply jaundiced, nausea and vomiting occurred, the appetite was lost, and weakness became progressive. The next day she became apathetic and lapsed into coma two days later. There were no previous signs or symptoms of hepatic or biliary tract disease.

The patient was well nourished. She had hypertrophic arthritis of the hands. The temperature was 99.0 F., pulse 96 and respiration 22. The heart and lungs were normal. The blood pressure was 118 systolic and 88 diastolic. The liver dulness was diminished. The remainder of the physical examination was negative.

The day after admission, the icterus index was 40. The van den Bergh test gave an immediate direct reaction. The retention of bromsulphalein in sixty minutes was 70 per cent. Nonprotein nitrogen was 44 mg. and urea nitrogen 28 mg. per hundred cubic centimeters of blood. During the next four days, in spite of dextrose, insulin and fluids, the course was down hill and she died with a terminal rise in temperature to 104.3 F. and a profuse perspiration over the entire body.



Case 1
Case 2
Case 3

Microscopic appearance of liver.

The autopsy was done at the patient's home in a neighboring town and only inspection of the abdominal cavity was permitted. The liver was high under the diaphragm, the size of a large orange. The surface was nodular, with many fine yellow areas interspersed among a reddish-brown tissue. A portion was removed for microscopic study. The gallbladder, ducts and pancreas were normal. Microscopically there was seen extensive necrosis of the parenchyma with diffuse increase in connective tissue and compression of the liver lobules into nodular formation, very similar to case 2.

This elderly woman had no previous hepatic or biliary disease. Acute toxic cirrhosis developed after taking 14 grains (0.9 Gm.) of "Farastan" daily for about four months. No other etiologic agent could be demonstrated.

COMMENT

A study of the cases of cinchophen poisoning in the literature reveals that the toxic manifestations have no relation to the amount of the drug ingested. Thus, the patient of Evans[7] took only 15 grains (1 Gm.) the second patient of DeRezende only 3 Gm. and the patient of Lind[19] about 5 Gm. Conversely, Hench and Rowntree, discussing Rabinowitz's[12] cases, report a patient who took large amounts (from 40 to 90 grains, or 2.6 to 6 Gm.) daily for a period of eighteen years without untoward effect. Rabinowitz suggests that certain predisposing factors exist which sensitize the liver parenchyma to the toxic action of cinchophen compounds. Among these factors he names gallbladder disease, cirrhosis of the liver, chronic alcoholism, pregnancy, chronic nephritis and a past history of jaundice. Again, other cases (here reported) give no clinical, laboratory or postmortem evidence of liver dysfunction. So-called safe methods of giving the drug, as intermittently, with sodium bicarbonate and the like are not without hazard, since Willcox[9] and Lowenthal[20] observed toxicity arising following these measures.

Owing to the increased number of cases of toxic hepatitis being reported in the literature due to cinchophen compounds, and to the lack of a safe method of administering the drug, it would seem logical to employ, as analgesics, compounds devoid of the insidious danger of poisoning.

SUMMARY AND CONCLUSIONS

1. Eighty-nine cases of hepatotoxicosis due to cinchophen or its congeners were collected in the literature. Fifty-two patients recovered. Thirty-seven fatal cases are reported with the diagnosis confirmed by autopsy in thirty cases. I observed three additional fatal cases, with postmortem examination.
2. Cinchophen and its compounds exert a destructive toxic effect on the hepatic parenchyma of certain sensitized persons. The essential clinical and pathologic observations are those of a specific type of toxic cirrhosis.
3. It seems apparent that the extensive employment of cinchophen compounds in the treatment of "arthritis" should be abandoned in favor of less hazardous preparations.

Harries Building.

DIABETIC COMA WITH BLOOD SUGARS ABOVE ONE THOUSAND MILLIGRAMS: REPORT OF THREE CASES WITH RECOVERY FOLLOWING TREATMENT

Charles J. Haines, M.D., and Reuben Davis, M.D.
Philadelphia

A case of diabetic coma with a blood sugar of 900 mg. per hundred cubic centimeters of blood was reported recently by Gray and Sansum.[1] Attention was drawn to the relatively few cases that have been reported in which recovery followed such a marked hyperglycemia. They were able to find only three cases besides their own. There can be no doubt that such cases are rare, but we feel that if all the unreported cases were collected the number would be somewhat increased. We here report three cases that were successfully treated in the metabolic ward of the Philadelphia General Hospital during the past five years.

Case 1.—M. M., a woman, aged 58, white, was admitted in coma, with no history of diabetes. Members of the family stated that in the past six months she had lost 40 pounds (18 Kg.), in spite of a voracious appetite, and that she had frequently complained of weakness. There was also a history of thirst and polyuria. Two days before admission she became nauseated and vomited several times. She had been in coma eight hours before she arrived at the hospital.

The temperature was 96 F.; the pulse, 150. Respirations were 35. The blood pressure was 80 systolic and 25 diastolic.

Breathing was Kussmaul in type. There was markedly decreased intra-ocular tension. There was a heavy odor of acetone on the breath. The lungs were clear. The heart sounds were distant and quite rapid. There were no murmurs. Examination of the abdomen did not reveal palpable organs or masses. The extremities were limp and flaccid.

The blood sugar was 1,120 mg. per hundred cubic centimeters of blood on admission; the urea nitrogen of the blood, 45 mg., and the creatinine, 1.5 mg. The urine was strongly positive for sugar, acetone and diacetic acid, with a heavy trace of albumin and many hyaline and granular casts.

Examination of the blood revealed: Red blood cells, 3,500,000; hemoglobin, 13.6 Gm.; white blood cells, 13,600; polymorphonuclears, 87 per cent; lymphocytes, 13 per cent.

The Wassermann reaction of the blood was reported negative in all antigens.

In addition to blankets and hot water bottles, soap sud enemas, gastric lavage, digitalis hypodermically, and hypodermoclysis of 1,500 cc. of 5 per cent sodium bicarbonate[2] and 1,500 cc. of physiologic solution of sodium chloride, the patient received 230 units of insulin, 180 of which was given intravenously during the eight hours following admission. The patient became conscious during the night and was able to take fluids and orange juice by mouth. Blood sugar determinations, by the Folin-Wu technic, were as follows: 1,120 mg. at 8:30 a. m. (on admission); 960 mg. at 11 a. m.; 800 mg. at 1:45 p. m.; 560 mg. at 4:30 p. m.; 80 mg. at 11 p. m.; 478 mg. at 7 a. m., and 150 mg. at 7 a. m.

The patient was discharged in three weeks on a diet of 60 Gm. of protein, 220 Gm. of fat, and 80 Gm. of carbohydrate; with an insulin dosage of 15 units before breakfast and 10 units before supper, and a fasting blood sugar of 125 mg.

Case 2.—H. H., a woman, aged 30, a Negress, with no history of diabetes before the onset of coma, had been vomiting for two days and was comatose for twelve hours before admission. Symptoms of polyuria, polydipsia and polyphagia could not be obtained from the husband.

The temperature was 97 F.; the pulse, 160; the respiratory rate, 30.

Breathing came in long sighing gasps. The tongue and mouth were dry. The skin was parched and wrinkled. The eyeballs were soft. The pupils were unequal and did not react to light. Some impairment was found over the lower right side of the chest, with a few fine, moist râles. The heart was not enlarged to percussion. Heart sounds were rapid but regular; there were no murmurs.

Blood sugar on admission was 1,080 mg. per hundred cubic centimeters of blood, with a carbon dioxide combining power of 11 volumes per cent. The urea nitrogen of the blood was 21 mg. Examination of the urine showed 4.4 per cent sugar; the urine was positive for acetone and diacetic acid, with a heavy cloud of albumin and many hyaline and granular casts.

The Wassermann reaction of the blood was + + + + in all antigens.

Table 1.—*Blood Sugar and Carbon Dioxide Combining Power in Case 2*

Blood Sugar, Mg.		CO_2 Volumes, Per Cent	Time
1,080	(Folin-Wu technic)..	11	6:00 p. m. (on admission)
900	....	15	8:00 p. m.
332	....	20	10:30 p. m.
71	....	49	3:00 a. m.
140	....	63	7:00 a. m.
152	....	49	10:30 a. m.
203	....	60	3:00 p. m.

Treatment consisted of external heat, gastric lavage with 2 per cent sodium bicarbonate, soap suds enemas, hypodermoclysis of 1,000 cc. of 5 per cent sodium bicarbonate[2] and 1,000 cc. of physiologic solution of sodium chloride, with 500 cc. of 5 per cent sodium bicarbonate and 20 Gm. of dextrose by proctoclysis. During the night, from 6 p. m. until 7 a. m., the patient received 300 units of insulin, 100 of which was given intravenously as the initial dose. The patient was not conscious until the following afternoon, despite the fact that her blood sugar the next morning was 140 mg., and the carbon dioxide combining power 63 volumes per cent. She received a total of 50 units of insulin during the remainder of the day. The blood sugar and carbon dioxide combining power are given in table 1.

[1] Gray, P. A., and Sansum, W. D.: Diabetic Coma with Marked Hyperglycemia and Recovery, J. A. M. A. **97**: 230 (July 25) 1931.

[2] This procedure has been discontinued for the past two years, owing to an unfortunate slough which resulted from the conversion of sodium bicarbonate to sodium carbonate in the process of sterilization. At present sodium bicarbonate is given through a "Levin gastroduodenal" tube, which is left in place during the entire treatment of coma.

The patient was discharged on a diet of 60 Gm. of protein, 180 Gm. of fat and 100 Gm. of carbohydrate, with an insulin dosage of 10 units before breakfast and 10 units before supper, and a fasting blood sugar of 133 mg. per hundred cubic centimeters of blood.

Case 3.—C. R., a Negress, aged 46, was not known to have diabetes. The history obtained from the family was that for the past two months the patient had suffered from polyphagia, polydipsia, polyuria and nocturia and had lost 32 pounds (14.5 Kg.) during this time. No medical advice was sought until the onset of coma. The patient was comatose for eleven hours before admission to the hospital.

The temperature was 96.5 F.; the pulse, 120; the respiratory rate, 25; the blood pressure, 90 systolic and 50 diastolic.

Table 2.—*Insulin Given in Case 3*

Units			
40	Intravenously	10:45 p. m.	(on admission)
40	Subcutaneously	11:15 p. m.	
40	Subcutaneously	11:50 p. m.	
40	Subcutaneously	12:20 p. m.	
40	Subcutaneously	1:20 a. m.	
50	Subcutaneously	2:00 a. m.	
30	Subcutaneously	4:00 a. m.	
20	With orange juice, 275 Gm.	7:00 a. m.	
Total, 300			

The patient was in deep coma; there was no response to external stimuli. Respirations were rapid, full and regular. There was a urinoid odor to the breath, but no acetone was detectable. The eyeballs were soft and compressible. The mouth was dry and the teeth were dirty. The skin was quite dry and dehydrated. Movements of the chest were diminished on the right side. The percussion note was impaired in both axillae. Breath sounds were harsh in the right axilla, with a few crackling râles. The pulse was almost imperceptible, and there was no enlargement of the heart on percussion. Sounds were rapid and distant. There were no audible murmurs. There was some rigidity in the lower left quadrant of the abdomen. There was a profuse purulent vaginal discharge, with excoriation and ulceration of the vulva of the left side. The extremities showed nothing of interest except marked diminution of the reflexes.

Table 3.—*Blood Sugar and Carbon Dioxide Combining Power in Case 3*

Blood Sugar, Mg.		CO_2 Volume, Per Cent	Time	
1,056	(Folin-Wu technic)	18	10:50 p. m.	6/12/31
1,296		12	11:55 p. m.	
960		14	11:30 p. m.	
600		14	3:30 a. m.	
338		25	5:30 a. m.	
140		19	7:00 a. m.	6/13/31
131		23	10:00 a. m.	
70		37	3:00 p. m.	
232		57	9:00 p. m.	
208		61	7:00 a. m.	6/14/31

Blood sugar on admission was 1,056 mg. per hundred cubic centimeters with a carbon dioxide combining power of 18 volumes per cent. One hour and five minutes later the blood sugar had risen to 1,296 mg. per cent and the carbon dioxide fallen to 12 volumes per cent in spite of the administration of 120 units of insulin, 40 of which had been given intravenously. The urea nitrogen of the blood was 55 mg.

Examination of the blood revealed: Red blood cells, 5,500,000; hemoglobin, 16.4 Gm.; white blood cells, 27,700; polymorphonuclears, 82 per cent; lymphocytes, 16 per cent; large lymphocytes, 2 per cent.

The urine was strongly positive for sugar, acetone and diacetic acid, with a heavy trace of albumin and myriads of leukocytes (catheterized specimen).

The Wassermann and Kahn reactions of the blood were strongly positive.

Treatment consisted of blankets and hot water bottles, soap suds enemas, gastric lavage of 2 per cent sodium bicarbonate, hypodermoclysis of 3,000 cc. of physiologic solution of sodium chloride, digitalis and caffeine sodium benzoate hypodermically, sodium bicarbonate, 30 grains (2 Gm.), every hour through the Jutte tube until 11 a. m. the next day, and insulin as shown in table 2.

The blood sugar determinations and the carbon dioxide combining power are shown in table 3.

June 13, 1931, a diagnosis of pneumonia was quite apparent and a roentgenogram taken with a portable machine showed consolidation of the lower portion of the right upper lobe. Urea nitrogen of the blood had risen to 80 mg., with a creatinine determination of 3.4 mg. Since 4 a. m. the patient had been noisy and irrational, but at 5 p. m. had become quiet and was resting comfortably. The patient received 830 Gm. of orange juice in addition to 2,500 cc. of physiologic solution of sodium chloride by hypodermoclysis during the day.

June 14, fasting blood sugar was 208 mg.; the carbon dioxide combining power, 61 volumes per cent; urea nitrogen, 33 mg., and creatinine 1.4 mg.

Recovery from the pneumonia was uneventful and the patient was discharged forty-five days after admission on a diet of 60 Gm. of protein, 150 Gm. of fat and 100 Gm. of carbohydrate, with an insulin dosage of 8 units before breakfast and 5 units before supper.

SUMMARY

1. In three cases of diabetic coma with very high blood sugar, recovery occurred.
2. We believe that clinicians have failed to report other cases.
3. We warmly endorse the administration of sodium bicarbonate as an adjunct to insulin. In our experience, we have never seen harmful results from its administration by means of a stomach tube during the treatment of diabetic coma.

803 Pine Street.

DERMATITIS VENENATA DUE TO SHOE LEATHER

Nelson Paul Anderson, M.D., and Samuel Ayres, Jr., M.D.
Los Angeles

Lewis[1] has recently reported two cases of dermatitis affecting the feet and ankles, in which the causative agent was definitely proved to be shoe leather. The following case is reported to point out that not all eruptions of the feet are of fungous origin and that other factors must be considered.

REPORT OF CASE

W. S., a man, aged 60, seen, Jan. 12, 1932, had an eruption on the feet which had been present for the past seven months. He had been under the care of several physicians, who had made various diagnoses, including eczema and fungous infection, and had applied various ointments together with twelve ultraviolet ray treatments.

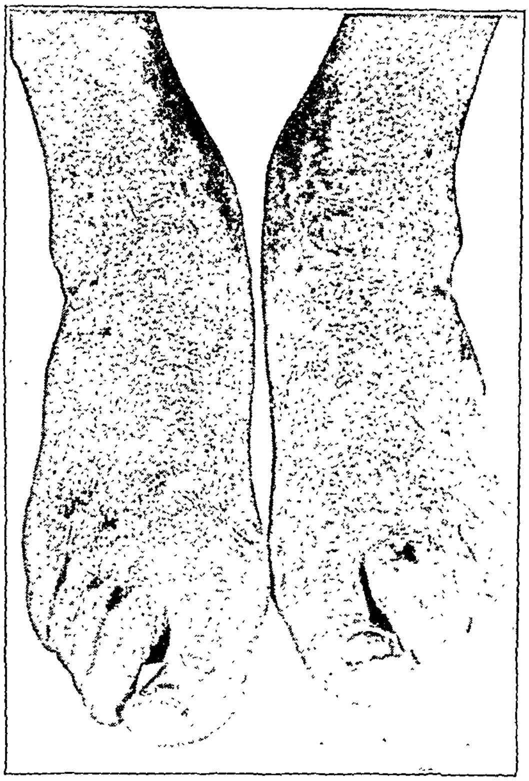
There was a marked erythema of both feet on the dorsum, sides and ankles, extending up the ankle to the level of the shoe top and abruptly ending. There were large, thick scales, the size of a finger nail, and crusts beneath which there was a good deal of fissuring and oozing. There was no maceration or scaling between any of the toes.

The following history was obtained: In February, 1931, the patient purchased a new pair of black shoes which were ordered from a distant manufacturer. These shoes were worn on Sundays and occasionally in the evenings. The last week in June, 1931, an eruption began on the dorsum of the feet as a redness, which shortly became vesicular and started to ooze. He continued to wear these shoes at occasional intervals. His feet became so swollen and sore that for three or four days at a time it was impossible to wear any shoes. About every seven to ten days the entire process of itching, burning, redness, swelling and oozing would be repeated, although the feet were never entirely free from the eruption since the onset. About six or eight weeks previous to the time we first saw him, he noticed a moderately erythematous, scaly eruption on the wrists and forearms. He had never had the shoes dyed, nor did he believe that his feet had ever been wet while wearing the shoes. His feet, as a rule, perspired only moderately.

From the Department of Dermatology, College of Medical Evangelists.

[1] Lewis, G. M.: Dermatitis Venenata from Shoe Leather, Arch. Dermat. & Syph. **24**: 602 (Oct.) 1931.

A leather piece the size of a postage stamp was removed from one of the shoe tongues, the inner cotton fabric lining was removed from the leather, and both pieces were applied to the inner surface of the forearm where the skin was normal. These were removed at the end of twenty-four hours and no reaction was present. The following day both areas were markedly erythematous with small vesicles and since then these two test areas had passed through the same stages of eruption as noted on the feet. These positive "patch test" reactions were still visible six weeks later. A control patch test done on a normal person with the same leather and lining was negative. No fungi were demonstrated from between the toes or from the scales.



Dermatitis venenata due to shoe leather.

Treatment consisted of avoidance of this particular pair of shoes and the application of soothing lotions and ointments. The arms have entirely cleared, the feet are nearly well, and there has been no exacerbation since the patient stopped wearing the shoes.

2007 Wilshire Boulevard.

Economic Burden of Mental Disease.—The economic burden due to mental disease has been called to the attention of the people of New York State during the past eight years by three campaigns on behalf of proposals for bond issues for the building of state institutions. The proposals, all of which were approved by the voters, provided, in 1923, for a bond issue of $50,000,000 for state hospitals and other institutions; in 1925, for a bond issue of $100,000,000 for state institutions and other improvements, to be made available at the rate of $10,000,000 a year; and in 1930, for a bond issue of $50,000,000 for state hospitals and state prisons. About $90,000,000 of the proceeds of these bond issues has been or will be devoted to the construction of hospitals for patients with mental disease. Another phase of the burden was emphasized by the appropriation, in 1931, of nearly $24,000,000 for the maintenance of patients with mental disease in the hospitals of the New York State Department of Mental Hygiene.—Pollock, H. M.: Economic Loss to New York State and the United States on Account of Mental Disease, 1931, *Ment. Hyg.* **16**:289 (April) 1932.

Special Article

THE PRESENT STATUS OF VITAMIN B_2 (G)

HISTORICAL SURVEY

BARNETT SURE, PH.D.
FAYETTEVILLE, ARK.

[EDITORIAL NOTE.—The following article is one of a series on the Present Status of the Knowledge of Vitamins, prepared under the auspices of a committee composed of Morris Fishbein, chairman, Lafayette B. Mendel and Julius Hess, representing a joint committee of the Council on Pharmacy and Chemistry and the Committee on Foods. These articles have been considered by the Council on Pharmacy and Chemistry and by the Committee on Foods and are published under their auspices. The opinions expressed are those of the authors and not necessarily the opinions of the Council on Pharmacy and Chemistry or the Committee on Foods.]

During the last few years it has been definitely established that the dietary factor which McCollum and Kennedy[1] in 1916 termed water soluble B, generally recognized as a growth-promoting and appetite stimulating substance, is a mixture of vitamin B or vitamin B_1 and G or B_2. One of these is relatively thermolabile and has antineuritic and growth-promoting properties; the other is more stable after heating under pressure and also possesses growth-promoting properties and functions in the prevention and cure of pellagra-like symptoms in the rat. The former is also referred to as the antiberiberi, and the latter as the antipellagric vitamin. The nomenclature of these two dietary essentials has not yet been finally settled. The American biochemists have adopted the letter B for the antiberiberi factor and the term G for the antidermatitis vitamin.[2] In this communication the term B_2, tentatively adopted by the biochemists of England, will be employed to represent the antipellagric vitamin.[3]

As early as 1919, Mitchell[4] wrote an excellent review of the literature on the subject of vitamin B and questioned the identity of the antineuritic factor of Eijkman,[5] Grijns[6] and Funk[7] with the growth-promoting substance of McCollum and Kennedy.[1] Although Mitchell did not submit any experimental evidence, his critical analysis was so sound that his paper served as a great stimulus for further fruitful research. His arguments were as follows: 1. The green vegetables, such as cabbage and spinach, are rich sources of water-soluble B, compared with whole cereal grains, but are low in the concentration of the antineuritic factor. The carrot was given as another illustration of a fairly rich source of the growth-promoting factor for the rat but deficient in the antineuritic substance essential for the prevention and cure of polyneuritis in the pigeon.

2. The paralytic symptoms observed in rats on vitamin B-deficient diets are not specific for this avitaminosis. 3. There is a lack of carefully controlled experiments on solubility and thermostability of the two substances, so it is impossible to make definite conclusions as to their identity or nonidentity.

In 1920 there appeared a paper by Emmett and Luros,[8] entitled "Are the Antineuritic and the Growth-Promoting Water-Soluble B Vitamins the Same?" in which they presented evidence that the "antineuritic factor (pigeons)" is totally destroyed when heated for two hours at 120 C. and 15 pounds pressure, while the "water-soluble B vitamine (rats)" appears to be stable to heat under such treatment. From these observations they tentatively suggested that the antineuritic (pigeons) and the growth-promoting (rats) factors are not the same and that "it would be better to consider them as different until there is further proof to the contrary." This work constituted the first experimental evidence concerning the dual nature of what is now known as the vitamin B complex, but apparently this paper did not for some years receive the attention it duly deserved.

In 1923, Levene and Muhlfeld[9] reported a considerable variation in distribution of the antineuritic and growth-promoting principles in various samples of brewers' and bakers' yeasts, from which results they concluded that these two dietary essentials may not be identical.

In February, 1926, Smith and Hendrick[10] presented the first convincing evidence, followed later in the same month by Goldberger, Wheeler, Lillie and Rogers,[11] demonstrating the dual nature of vitamin B.

While engaged in the study on the effect of dietary deficiencies on experimental tuberculosis in the albino rat, Smith and Hendrick found that a diet composed of 40 per cent rolled oats (6 per cent protein) plus 10 per cent purified casein, fortified with vitamin A[12] and inorganic salts, failed to produce normal growth. However, such a dietary regimen was successfully supplemented by dried brewers' yeast autoclaved for six hours at 15 pounds pressure, which procedure completely destroyed vitamin B. They therefore concluded that dried brewers' yeast contains some factor other than vitamin B.

Goldberger and his associates demonstrated that autoclaved dried bakers' yeast (Fleischmann's wort-grown, low temperature), as a source of "water-soluble B" produced in rats rapid loss of weight, with or without polyneuritis, and, although an alcoholic extract of corn meal did alleviate or cure polyneuritis in the rat, the slight initial growth was followed by an arrest and subsequently by a decline of growth. However, if rats, fed a diet satisfactory in every respect with the exception of water-soluble B, were given a combination of small proportions of the autoclaved yeast and the extract of maize meal, the animals made considerable growth. The autoclaved yeast, as well as fresh lean beef or dried lean beef, they found potent for the prevention and cure of human pellagra and a pellagra-like disease in the dog, black tongue. They provisionally named this relatively stable dietary substance P-P, or pellagra-preventive. Young rats, fed a diet containing 20 per cent of dried or fresh lean beef as the only source of vitamin B, declined in weight and died with or without polyneuritis. When signs of polyneuritis began to appear, if there was introduced in such a diet 5 per cent of the alcoholic corn extract (40 per cent of which, as the only source of vitamin B in the ration, did not permit growth in the rat), the animals, if they had not reached the premortal state, were cured of the polyneuritis and resumed growth. These investigators therefore concluded that the alcoholic extract of maize contains an essential that cures polyneuritis in the rat and, while not growth-promoting in itself, permits or promotes growth when combined in a diet otherwise complete for growth except for "water-soluble B" with a suitable proportion of a P-P containing substance, such as autoclaved yeast or beef (which in itself, within certain limits, neither prevents polyneuritis nor permits growth).

In May, 1926, Goldberger and Lillie[13] described their experiences in the experimental production of pellagra-like symptoms in the rat on a diet in which an 85 per cent alcoholic extract of corn served as the only source of vitamin B. The following is a description, in part, of the main symptoms they encountered:

> After a variable period following the arrest of growth, there has been observed in many of the animals so fed a tendency of the lids of one or both eyes to adhere together with, in some instances, an accumulation of dried secretion on the margin of the lids. [Following the appearance of the ophthalmia or at the time the eye lesions made their appearance, alopecia developed in most of the animals, and in some animals it has led to almost complete denudation of the head, neck and trunk.] With or without such loss of fur some of the animals have developed a dermatitis at one or more of the following sites: ears, front of neck and upper part of chest, forearms, backs of forepaws, shins, and backs of the hind paws. This dermatitis, particularly as it has affected the paws, forearms, neck and ears, has been sharply outlined as bilaterally symmetrical. . . . The ears seemed definitely reddened and thickened with what appeared to be a yellowish incrustation of dried serum. In healing, desquamation took place, leaving the skin of the pinna with a polished, glistening, somewhat parchment-like appearance. . . . In the cases in which the backs of the forepaws were affected, the skin was red and rough and, after healing, but before the renewal of the normal, fine, silky fur, the skin had a pale pink, glistening, new-skin appearance. The backs of the hind paws, when affected, presented at first an appearance as of a matting of the silky fur of this part, which then looked dull and thickened. Later this matted layer of fur began to fissure and crack and then gradually desquamated, leaving a denuded pale pink, glistening skin.

The shortest period for the production of this dermatitis was approximately seven weeks. In addition to the skin lesions, Goldberger and Lillie found a stomatitis comparable to that found in pellagra. These pellagra-like symptoms in the rat were cured by the inclusion in the diet of a fullers' earth adsorbate of yeast, which resulted in the clearing up of the lesions and was accompanied by a resumption of growth. The following are the conclusions of these investigators: "We may conclude, therefore, that while it is, on the whole, highly probable that the pellagra-like condition in the rat is the analogue of pellagra in man, it will require additional evidence to establish this beyond reasonable doubt."

[13] Goldberger, Joseph; and Lillie, R. D.: Pub. Health Rep. **41**: 1025 (May 28) 1926.

In 1917, Chittenden and Underhill[14] reported a dietary disease in the dog which closely resembles human pellagra. The nitrogen of the diet on which this disease was produced was derived mainly from boiled peas. The rest of the constituents of the ration contained cracker meal and cottonseed oil. The main symptoms noted were anorexia, intensive salivation, foul mouth, bloody diarrhea and convulsions. From the recent observations of Underhill and Mendel[15] it is evident that this canine disease is of an entirely different character from the black tongue described by Goldberger and Wheeler.[16] Underhill and Mendel found the curative agent for their disease to be contained in butter fat, carrots and carotene and have concluded that the dietary factor deficient in their disease is probably associated with the carotenoids, while Goldberger and Wheeler[16] concluded that the missing constituent in their diet on which black tongue is produced is the antipellagric factor found in yeast and lean beef.

In August, 1926, Hauge and Carrick,[17] independently, made a differentiation between the water-soluble growth-promoting and antineuritic substances, based on their experiences in feeding experiments with baby chicks. They found that the particular yeast they employed was poor in the antineuritic substance but rich in the water-soluble growth-promoting substance, while corn was relatively rich in the antineuritic substance but poor in the growth-promoting substance. The authors stated: "It is concluded that the antineuritic vitamin and the water-soluble growth-promoting vitamin are not identical, although they may occur in the same food."

In 1927, Chick and Roscoe[18] of England corroborated the main observations of Goldberger and Lillie,[13] designating the stable factor as B_2. They suggested that they might be dealing with more than one dietary deficiency, for animals deprived of B_2 occasionally remained stunted in growth but showed no especial dermatitis.

In 1927 there also appeared the confirmatory evidence of Salmon[19] and of Sherman and Axtmayer[20] of this country.

Salmon prepared a fullers' earth fraction which prevented experimental polyneuritis of pigeons but did not induce growth of rats. The residue, which possessed extremely weak antineuritic or growth-promoting action when fed alone, had a marked growth-promoting action when added to the antineuritic fraction.

Salmon also found the seeds of the velvet bean and soy bean to have a higher antineuritic value than the leaves of these legumes, but his comparative tests showed these leaves to be more potent than the seeds in the growth-promoting action.

Sherman and Axtmayer[20] reported a supplementary relation between whole wheat and dried skimmed milk but no such supplementary relation between the dried milk and the autoclaved yeast. Hence, they concluded that milk is relatively richer in vitamin B_2 than in vitamin B_1.

In 1930, Norris and Ringrose[21] reported the occurrence of "a pellagrous-like" syndrome in chicks, which they cured with autoclaved yeast.

PHYSICAL AND CHEMICAL PROPERTIES

Thermostability.—In 1930, Chick and Copping[22] and Chick and Roscoe,[23] in quantitative studies, demonstrated that the "so-called stable antipellagric factor" becomes unstable in an alkaline medium when heated for certain periods at a temperature of from 122 to 125 C. At p_H 5.0 no loss in vitamin B_2 potency could be detected on heating yeast for two hours at from 90 to 100; about 50 per cent was lost on heating the yeast for from four to five hours at 123; at p_H 3.0 the loss was the same with yeast and with a yeast extract. When the reaction was alkaline (p_H 10-9.5), about 30 per cent of the vitamin B_2 originally contained in the yeast extract was lost in ten days at room temperature (summer). On heating for two hours at from 98 to 100 (p_H 8.3), the loss was about 50 per cent and on autoclaving for from four to five hours at 122-125 (p_H 8.3-10), between 75 and 100 per cent.[23]

Fractionation and Concentration.—In 1928, Salmon, Guerrant and Hays[24] reported their results of studies on the effect of hydrogen ion concentration on adsorption of the active factors of vitamin B complex by fullers' earth and found that the maximum adsorption of B_1 was obtained in a zone between p_H 3.0 and p_H 5.5, with the optimal point at p_H 4.0. The maximum adsorption of B_2 by fullers' earth occurred at p_H 0.08, the most acid solution tested.

In 1927, Kinnersley and Peters[25] perfected a method for the preparation of a vitamin B concentrate from yeast, which can be summarized as follows: After making an aqueous extract, inert ingredients are removed first with neutral lead acetate, followed by mercuric sulphate. After the separation of the metals from the solutions, the filtrate is brought to a p_H of 7.0 with sodium hydroxide and the vitamin adsorbed on purified norite, which is an activated charcoal. The vitamin is then released from the norite by repeated extraction with tenth normal hydrochloric acid.

In 1928, Chick and Roscoe[26] stated that they found this concentrate, which Kinnersley and Peters[25] named torulin, to be very potent in B_1 but practically deficient in B_2 and, employing this B_1 extract, perfected a method for the determination of B_2 in food materials, which will be described briefly later in the text.

In a recent attempt to separate vitamin B_2 from vitamin B_1 in yeast, Chick and Roscoe[27] found that vitamin B_2 is insoluble and vitamin B_1 is soluble, in alcohol of 92 per cent by weight. The method used to produce a separation with strong alcohol destroyed vitamin B_2. The attempt to prepare a vitamin B_2 concentrate free from vitamin B_1 by the use of alcohol resulted in failure.

Reaction with Nitrous Acid.—In 1928, Levene[28] reported that by means of nitrous acid the activity of the heat-stable factor is destroyed, whereas that of the heat-unstable factor remains intact. These observations were not confirmed by Chick,[29] in 1929, who found that a vitamin B_2 preparation from yeast possessed the same potency after as before treatment with nitrous acid, when tested on young rats. The recent conclusions of Sherman and Whitsitt[30] are essentially in harmony with those of Chick; namely, that vitamin B_2 in itself is stable toward nitrous acid. They state, however, that they found that "certain conditions of loss of vitamin B_2, as in the work of Levene and in certain parts of our own work, may perhaps better be considered as indicating more or less destruction of the newer and not yet clearly defined factors which are now being found to be essential for the growth of rats." The final conclusion of the latter investigators is that vitamin B_1 behaves in vitro more like a nitrogenous base and vitamin B_2 more like a neutral organic substance.

RELATION TO NUTRITION

Quantitative Biologic Method of Determination.—In 1928, Chick and Roscoe[26] developed the following biologic method for the evaluation of vitamin B_2 in food materials: Young rats, about 4 weeks old and *weighing from 40 to 50 Gm., are placed on a basal diet,* satisfactory in every respect with the exception of vitamin B. They are kept on this ration for ten days and are then separated in individual cages with raised screens to prevent coprophagy.[31] After a preliminary period of two weeks of vitamin depletion, a daily dose of 0.1 cc. of the antineuritic concentrate of Kinnersley and Peters[25] (equivalent to 0.6 Gm. of the original yeast, dry weight) is administered to provide an abundance of vitamin B_1, and only negligible traces of vitamin B_2. After from three to four weeks from the beginning of the experimental feeding, the young rat is ready for the assay of vitamin B_2 in any material. The minimum dose which gives an average weekly increase of from 10 to 12 Gm. is considered the vitamin B unit for comparison.

In 1929, Bourquin[32] described a biologic procedure which is a modification of the quantitative method of Sherman and Spohn[33] developed for the vitamin B complex. *Her diet consisted of purified casein, 18;* Osborne and Mendel salt mixture, 4; butter fat, 8; cod liver oil, 2; corn starch, 68, a part of which carried an alcoholic extract of whole wheat for each hundred grams of diet as a source of B_1. The whole wheat presumably furnished insignificant amounts of B_2. Young rats, from 28 to 29 days of age, are placed on this diet for from fourteen to eighteen days and are confined in individual cages with raised screen bottoms until they cease to grow, when the test period is begun. One animal from each litter is kept on the basal diet minus the alcoholic extracts of whole wheat which serves as a negative control. The gain in weight of the test animals over that of the controls indicates the relative amounts of vitamin G present in the materials fed. The vitamin B_2 unit is described as the average gain of 3 Gm. weekly per animal for a period of eight weeks, or a gain of 24 Gm. per animal for the test period.

Recently Munsell[34] reported that more regular and dependable results can be obtained with the Bourquin procedure if 30 per cent of white corn as a source of vitamin B_1 is used in the diet. The author claims that this amount of white corn in the diet furnishes an abundance of B_1 and a neglible amount of B_2.

Distribution of Vitamin B_2 in Food Materials.—Employing the method of Chick and Roscoe,[26] Aykroyd and Roscoe[35] list the distribution of vitamin B_2 in foodstuffs in the following descending order: dried ox liver, dried yeast, autoclaved yeast, meat (dried steak), milk solids, dried egg yolk, wheat germ, wheat bran, wheat pollard, dried peas, whole wheat (Manitoba), whole wheat (English), whole maize (white), whole maize (yellow), maize germ meal, wheat endosperm and maize endosperm.

Hunt[36] found that wheat and corn contain approximately the same amounts of vitamin B_1 and B_2 but states that they are richer in B_1 than B_2.

Hunt and Krauss[37] reported that milk from cows under winter feeding conditions was potent in B_2 and relatively poor in B_1.

Recently Hetler, Meyer and Hussemann[38] published a detailed study of quantitative determinations of the content of B_1 and B_2 in cereals. They found that a diet including as much as 50 per cent of any of the cereals would supply enough vitamin B_2 for approximately normal growth, while 25 per cent of any of the cereals provided enough vitamin B_1. I[30] found rice polishings to be abundant in vitamin B_2 for growth. *This is confirmed by Hetler and her associates.*[38]

Vitamin B_2 and Anorexia.—Burack and Cowgill[40] recently reported that in the anorexia developed in dogs *on diets deficient in the vitamin B complex, either (1)* the antineuritic vitamin is the sole etiologic agent or (2) another substance, not vitamin B_2, is required to supplement the antineuritic factor in preventing and correcting the anorexia they investigated.

Graham and Griffith[41] emphasize the importance for normal appetite of both the antineuritic vitamin and another factor which is found in autoclaved liver. Whether this factor contained in autoclaved liver is vitamin B_2 still remains to be demonstrated.

Vitamin B_2 and Lactation.—In 1924 I demonstrated that the albino rat requires considerably more of the vitamin B complex for lactation than for growth. These results were followed by quantitative data in 1927. The observations in our laboratory have been confirmed by Macy and her co-workers[42] and by Evans and Burr.[43] The latter investigators, however, maintained that "lactation delinquency is due to inadequate antineuritic vitamin and in no degree to inadequate growth-promoting vitamin B.[43] Our results, on the other hand, demonstrated that both factors, B_1 and B_2, are essential in much greater amounts for lactation than for growth.[30] The apparent discrepancy probably lies in the failure of Evans and Burr with their biologic technic to find vitamin B_2 in "tikitiki,"[44] which is now reported by Hetler, Meyer and Husselman[38] to contain appreciable amounts of the antipellagric factor. The claims, however, of Hetler and her associates that more of B_2 than of B_1 is essential for lactation are not convincing since their "tikitiki," which furnished the B_1 factor, according to their own statement supplied appreciable quantities of the B_2 vitamin. Further carefully controlled quantitative experiments are necessary to establish this point definitely.

The Influence of Vitamin B_2 Deficiency on Pathologic Changes in Blood and Tissues.—Smith[45] and I recently reported that neither arrest of growth, loss of weight, nor accompanying dermatitis, as a result of vitamin B_2 deficiency, had any influence on apparent or true blood sugar or alkali reserve of the albino rat. There was a reduction, however, in the glycogen content of the liver in animals that had lost considerably in weight during periods of inanition. Although vitamin B_1 per se produces a marked reduction in liver glycogen,[46] it still remains to be demonstrated whether vitamin B_2 per se produces a similar physiologic effect.

That pellagra is an avitaminosis, produced by a deficiency of a dietary factor, associated with the vitamin B complex, is now generally recognized. Recently, however, Bliss[47] has advanced the theory that pellagra is an iron-deficiency disease and claims that the curative agent of the vitamin-containing foods employed by Goldberger and other investigators is not vitamin B_2 (G) but iron. Although it has not yet been conclusively established whether the pellagra-like disease in the rat is the analogue of human pellagra, it may be of interest to mention here that the secondary anemia that we have encountered in this avitaminosis in our laboratory[48] in rats in which dermatitis was produced has no connection with a mineral deficiency, since our diets had an abundance of ferric citrate and since in such anemia we found no response to the administration of the ash from yeast.

We did not find any significant changes in the total and differential leukocyte count in vitamin B_2 deficiency.[48]

In 1928, Salmon, Guerrant and Hays[49] confirmed the work of Goldberger and Lillie,[13] but in addition reported the presence of a gram-positive coccus from skin and arthritic lesions, parenchymatous organs and the walls of the intestine.

In 1929, Sherman and Sandels[50] described their experiences with vitamin B_2 deficiency in the albino rat. Their observations were similar to those reported by Goldberger and Lillie[13] and by Chick and Roscoe.[18]

In 1928, Findlay[51] described the following pathologic changes in vitamin B_2 deficiency: 1. Failure of growth occurs and, as terminal phenomena, loss of appetite and fall in body temperature. 2. Nervous symptoms are absent, but after from eight to ten weeks on the deficient diet there are lesions of the skin, buccal mucous membrane and tongue, which are very similar to those of pellagra in man. 3. Death occurs in from two to three weeks after the onset of the skin changes. 4. There is a papillomatous condition of the cardiac end of the stomach. 5. The histologic changes characteristic of inanition are present in rats as the result of a deficiency of vitamin B_2. 6. Hypertrophy of the suprarenals occurs in rats lacking either vitamin B_2 or vitamin B_1.

Findlay[51] also found dermatitis preceding alopecia, vesicles, swollen collagen fibers, atrophy of elastic tissue and congestion of the small blood vessels in the cutis, atrophy of the testicles, and certain lesions of the tongue and the stomach. We were unable in our laboratory to confirm the occurrence of these changes.

Thatcher, Walker and I[52] observed that the lesions in the skin of the albino rat suffering from vitamin B_2 deficiency were not absolutely comparable with human pellagra. Hyperkeratosis and parakeratosis with ulceration occurred, which might have eclipsed the early picture. Rarefaction of the superficial corium, as well as the fibrolytic stage, mitoses and the erythematous change described by Denton[53] as occurring in human pellagra, were not observed. Congestion of the intestine, found in our laboratory, is an observation that can be correlated with pellagra. However, chromogenic urine and incontinence of urine, observed in some of our animals, are not prominent in human pellagra according to the experience of Thatcher[54] with numerous pellagrins. Furthermore, in our experience with experimental rat pellagra, diarrhea was not a prominent symptom, as in many pellagrins. Constipation was also not present. Salivation did not occur, as is reported by Sherman and Sandels.[50] Stomatitis, one of the main symptoms reported by previous investigators, was not present in our rats. Loss of weight was common, and anorexia occurred in the terminal stages of the avitaminosis. These are frequent symptoms in human pellagra. The presence of ophthalmia (in some animals) and the lack of involvement of the nervous system could not be correlated with the human disease.

In summarizing this work, Thatcher, Walker and I stated: "In our opinion, neither we nor other investigators preceding us have actually produced a disease in the rat comparable with human pellagra. All that can be said is that pellagra-like symptoms have been experimentally produced."

Day, Langston and O'Brien[55] have recently reported that cataracts, usually preceded by inflammatory changes in the lids and cornea, occur with regularity in young albino rats receiving a diet deficient in vitamin B_2. They state that further progress of such changes was stopped by the addition of vitamin B_2 to the diet.

Complexity of Vitamin B_2.—Recently Roscoe[56] produced experimental evidence to the effect that vitamin B_2 is a complex composed of two dietary essentials. She found that when egg white is given as a source of vitamin B_2, the lack of a third factor, which she tentatively termed Y, necessary for the normal growth of the rat becomes apparent. "This factor is present in autoclaved yeast extracts and in watercress, lettuce, spinach, and cabbage, but the amounts present in lettuce and etiolated cabbage leaves are less than in the dark green leaves tested, and the amount present in the onion bulb is still smaller."[56]

Recently we[57] found in our laboratory that there is no relation between the failure in growth and the incidence of pellagra-like symptoms in the rat, the dermatitis being prevalent in some animals that make normal growth, and absent in others that are first stunted in growth for weeks and months, and finally collapse following great losses of body weight. We therefore suggested from this study that the so-called vitamin B_2 (G) is composed of two dietary essentials: one, the deficiency of which produces pellagra-like symptoms in the rat, and another, the deficiency of which produces a decline of growth.

It is difficult to make any comparisons of our observations with those of Roscoe because of the differences in the dietary regimen. Neither are we justified at present in making final conclusions concerning the complexity of vitamin B_2. The work is still in the early experimental stage and needs further evidence of a more quantitative character in order to establish the differentiation clearly. For this reason, it seems to me that a final decision as to nomenclature of the "so-called antipellagric factor" should still be held in abeyance. Indeed, the vitamin B complex seems to be a fountain of vitamins, as is evidenced by the recent works of Williams and Waterman,[58] Hunt,[59] Reader,[60] and Carter, Kinnersley and Peters.[61]

Council on Physical Therapy

The Council on Physical Therapy of the American Medical Association has authorized publication of the following reports.
H. A. Carter, Secretary.

ACCEPTANCE OF SUNLAMPS

A Preliminary Statement

During the last six years the Council on Physical Therapy has devoted much time and effort to the question of ultraviolet radiation therapy. It has been one of the most complex problems presented to the Council. Because of the restricted number of diseases for which weak ultraviolet radiation is indicated, it was impossible for the Council to evaluate properly ultraviolet radiation therapy until the mass of evidence, for and against, had been investigated. During this period, many unfounded claims for the therapeutic effectiveness of ultraviolet radiation from sunlamps have been recorded in advertisements designed for the attention of the profession and the public.

Investigation requiring extensive study has been made by the Council in collaboration with physicists, numerous specialists in the field, and other scientists acting as consultants for the Council. The result of the work has shown that ultraviolet radiation emitted by "sunlamps" (one class of ultraviolet plus luminous radiators) has a definite but limited therapeutic value. The Council was also confronted with the task of testing the submitted sunlamps emitting these radiations in various degrees of intensity. In an adopted article entitled "Ultraviolet Radiation Useful for Therapeutic Purposes—Specification of Minimum Intensity or Radiant Flux," by Dr. W. W. Coblentz, the Council has definitely specified the types of ultraviolet radiation generators that possess sufficient ultraviolet energy to be of therapeutic value. Furthermore, the Council has drafted two lists of requirements to govern the advertising of ultraviolet generators to the public and the profession.[1]

Sunlamps, so called, are not to be confused with therapeutic ultraviolet generators designed for service in hospitals, clinics and offices of physicians. The therapeutic lamps are comparatively more powerful emitters of ultraviolet energy, while the sunlamps for unsupervised home use are often of low intensity, to avoid injury from overdosage. The term "sunlamp," or a similar name, is understood by the Council on Physical Therapy to mean a lamp that at a specified distance emits ultraviolet radiation not differing essentially from that of the clearest weather, midday, midsummer, midlatitude, sea level, natural sunlight, in total intensity and in spectral range of wavelengths extending from 2,900 to and including 3,130 angstroms and that shall not emit an appreciable amount of ultraviolet of wavelengths less than 2,800 angstroms.

Furthermore, the so-called sunlamp, acceptable to the Council, shall have an erythemogenic efficiency of not less than 20 per cent (on the basis of 22 per cent for Washington noonday June sunlight) and the total ultraviolet in the spectral range of wavelengths 2,900 to and including 3,130 angstroms shall not be less than the erythemogenic equivalent of 20 microwatts per square centimeter of homogeneous radiation of the wavelength (2,967 angstroms) of maximum erythemogenic effectiveness which equivalent is $(20:0.20=)$ 100 microwatts per square centimeter at a thermally comfortable operating distance (say 2½ feet) from the subject irradiated, as specifically defined in the Specification of Minimum Intensity in The Journal, March 26, page 1082.

From time to time, acceptances or rejections of sunlamps for home use will be published in the columns of the Council on Physical Therapy in The Journal. In accepting sunlamps, the attention of the profession is called to the following:

A. The Council on Physical Therapy definitely withholds acceptance of the postulatory principle of dual-purpose lighting, because it is highly theoretical and the promulgators of this idea have not presented acceptable clinical evidence to the Council substantiating its therapeutic or prophylactic value.

B. The Council on Physical Therapy declines to accept sunlamps if the manufacturer fails to state in all advertising matter and descriptive literature the distance between the lamp and the recipient required to equal the intensity of middday, midsummer, midlatitude, sea level, natural sunlight. Thus, in the acceptances that follow, the reader will note that the manufacturer has stated the distance the recipient should be from the sunlamp to receive the alleged benefits.

C. The manufacturers of acceptable sunlamps for home use have agreed to discontinue the objectionable claims such as that exposure to ultraviolet rays increases or improves the tone of the tissues or of the body as a whole, stimulates metabolism, acts as a tonic, increases mental activity, maintains health, or tends to prevent colds, because these claims have not been conclusively substantiated by experimental evidence.

D. The Council declines to sanction claims recorded in descriptive literature and advertising matter in which implication is made that the production of an erythema is unnecessary as a test of intensity; that suberythemal doses are sufficient for therapeutic benefit. The Council believes that, while such statements may be made in good faith, they merely open the way to fraud by irresponsible venders of alleged sources of ultraviolet radiation. Until further evidence is presented to prove otherwise, the Council declares that the erythema test is the only means of determining whether appreciable ultraviolet is emitted by the source.

In order that there can be no misunderstanding on the part of any one relative to the stand of the Council on the acceptance of sunlamps, the dual-purpose lighting and the suberythemal dosage, the aforementioned stipulations are given to the profession that it may better understand the problems confronting the Council regarding ultraviolet radiation therapy. The Council will give careful consideration to clinical evidence scientifically gathered by controlled experiments. This evidence should prove that radiation from sunlamps designed for use without medical supervision has other therapeutic benefits aside from the recognized prophylactic and curative effect on rickets and the assistance in the development of sound bones and teeth.

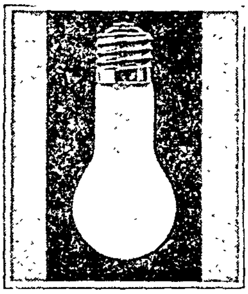
G. E. MAZDA SUNLIGHT LAMPS, TYPES S-1 AND S-2, ACCEPTABLE

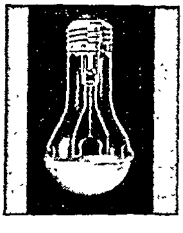
The Mazda Sunlight Lamps come in two sizes, S-1 and S-2. They are manufactured by the General Electric Company, Incandescent Lamp Department, Cleveland. The two lamps differ only in size and they may be described as a combination of a bulb containing two tungsten electrodes that are connected with a tungsten filament, while in the distal end of the bulb is a small pool of mercury. The current first flows only through the filament, but as the temperature increases the mercury vaporizes and an arc is formed between the ends of the tungsten electrodes. The process requires only a few seconds. However, it takes a few minutes for the lamp to begin radiating ultraviolet energy at its maximum efficiency. The mercury arc between the electrodes produces the major portion of the effective ultraviolet radiation. The result of the combination produces radiations in the visible, infra-red, as well as in the ultraviolet zones. The bulb is made of Pyrex glass, which absorbs most of the radiation in the ultraviolet region shorter than 2,800 angstrom units approximately. The Type S-2 lamp is much smaller than the Type S-1.



G. E. Mazda Sunlight Lamp Type S-1.

The Mazda Sunlight Lamps, Types S-1 and S-2, operate only on alternating current and in a specially constructed fixture. If direct current is the only supply available, additional equipment must be purchased at considerable expense. The manufacturer claims that these two lamps are designed to burn for an average period of 300 hours when employed in approved units or fixtures and that suitable adjustments will be made for any defect in manufacture.

The firm claims that "at a distance of thirty inches directly below the bulb of the Mazda Sunlight Lamp, Type S-1, or two feet directly under the Mazda Sunlight Lamp, Type S-2, the ultraviolet effectiveness is about equal to the midday, midsummer, midlatitude, sea level, natural sunlight. Increasing this distance decreases the effect quite rapidly; shortening the distance makes the ultraviolet more intense; when the distance is doubled it takes four times as long to get the same degree of sunburn. At half the distance, only one fourth of the time is required." The Council accepts the aforementioned statement on the basis of the most reliable evidence available. The distance between the lamp and the recipient is merely a close approximation and is subject to later modification when more exact data are available.



G. E. Mazda Sunlight Lamp Type S-2.

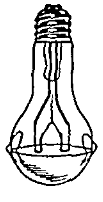
The company claims that clinical evidence, which it has submitted to the Council, proves that exposures of children to radiations emitted by the Mazda Sunlight Lamp, Type S-1, were effective in the protection of children against rickets. The Council agrees that if the treatment is given at the aforementioned distance between lamp and recipient the ultraviolet radiation emission is sufficient to be as effective in the prevention and cure of rickets as any other ultraviolet radiation emissions that are comparable to midsummer, midday, midlatitude, sea level, natural sunlight. With the distance between the lamp and recipient definitely indicated, the Council accepts this statement. The Council does not believe that sufficient evidence has been submitted to warrant acceptance of the statement that the Mazda Sunlight Lamps, Types S-1 and S-2, at ceiling distances or more from the recipient with its asserted suberythemal dose, furnishes sufficient ultraviolet radiation to prevent or cure rickets. The Council believes that further study and experimentation are necessary before proof of the value of suberythemal dosage of ultraviolet is sustained.

Based on the evidence that the radiations from the Mazda Sunlight Lamps at the prescribed distances may prevent rickets and promote the development of sound bones and teeth, the Council on Physical Therapy declares the G. E. Mazda Sunlight Lamps, Types S-1 and S-2, acceptable for inclusion in its list of accepted devices for one year.

WESTINGHOUSE MAZDA SUNLIGHT LAMPS, TYPES S-1 AND S-2, ACCEPTABLE

The Westinghouse Mazda Sunlight Lamps, Types S-1 and S-2, are manufactured and sold by the Westinghouse Lamp Company, 150 Broadway, New York City. The two lamps differ only in size, and they may be described as a bulb containing two tungsten electrodes that are connected with a tungsten filament, while in the distal end of the lamp is a small pool of mercury. The current first flows through the filament, but as the temperature increases the mercury vaporizes and an arc is formed between the ends of the tungsten electrodes. It requires only a few seconds for the arc to strike. However, it takes a few minutes for the lamp to begin radiating ultraviolet energy at its maximum efficiency. The mercury arc between the electrodes produces the major portion of the effective ultraviolet radiation. The result of the combination produces radiations in the visible, infra-red, as well as in the ultraviolet zones. The bulb is made of Pyrex glass, which absorbs most of the radiation in the ultraviolet region shorter than 2,800 angstrom units approximately. The Type S-2 lamp is about half the size of the Type S-1.

The Westinghouse Mazda Sunlight Lamps, Type S-1 and Type S-2, operate only on alternating current and in a special fixture. If the direct current is the only supply available, additional equipment must be purchased at considerable expense. The manufacturer claims that these two lamps are designed to burn for an average period of 300 hours when employed in approved units or fixtures and that suitable adjustments will be made for any defect in manufacture.



Westinghouse Mazda Sunlight Lamp Type S-2.

The firm claims that "at a distance of thirty inches directly below the bulb of the Westinghouse Mazda Sunlight Lamp, Type S-1, or two feet directly under the Westinghouse Mazda Sunlight Lamp, S-2, the ultraviolet effectiveness is about equal to the midday, midsummer, midlatitude, sea level, natural sunlight. Increasing this distance decreases the effect quite rapidly; shortening the distance makes the ultraviolet more intense; when the distance is doubled, it takes four times as long to get the same degree of sunburn. At half the distance, only one fourth of the time is required." The Council accepts the aforementioned statement on the basis of the most reliable evidence available. The distance between the lamp and the recipient is merely a close approximation and is subject to later modification when more exact data are available.

The company claims that clinical evidence, which it has submitted to the Council, proves that exposures of children to radiations emitted by the Westinghouse sunlight lamp, Type S-1, were effective in the protection of children against rickets. The Council agrees that if the treatment is given at the aforementioned distance between the lamp and the recipient, the ultraviolet radiation emission is sufficient to be as effective in the prevention and cure of rickets as any other ultraviolet radiation emissions that are comparable to midsummer, midday, midlatitude, sea level, natural sunlight. With the distance between the lamp and the recipient definitely indicated, the Council accepts this statement. The Council does not believe that sufficient evidence has been submitted to warrant acceptance of the statement that the Westinghouse sunlight lamps, Types S-1 and S-2, at ceiling distances or more from the recipient with its asserted suberythemal dose, furnishes sufficient ultraviolet radiation to prevent or cure rickets. The Council believes that further study and experimentation are necessary before proof of the value of suberythemal dosage of ultraviolet is sustained.

Based on the evidence that the radiations from the Westinghouse sunlight lamps at the prescribed distances may prevent rickets and promote the development of sound bones and teeth, the Council on Physical Therapy declares the Westinghouse Mazda Sunlight Lamps, Types S-1 and S-2, acceptable for inclusion in its list of accepted devices for one year.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

SODIUM AMYTAL (See New and Nonofficial Remedies, 1932, p. 91).

The following dosage forms have been accepted:

Ampoule Sodium Amytal, 0.25 Gm. (3¾ grains): Each ampule contains the stated amount of sodium amytal and is accompanied by a 2.5 cc. size ampule of distilled water.

Ampoule Sodium Amytal, 0.5 Gm. (7½ grains): Each ampule contains the stated amount of sodium amytal and is accompanied by a 5 cc. size ampule of distilled water.

Ampoule Sodium Amytal, 1.0 Gm. (15½ grains): Each ampule contains the stated amount of sodium amytal and is accompanied by a 10 cc. size ampule of distilled water.

LUMINAL-SODIUM (See New and Nonofficial Remedies, 1932, p. 85).

The following dosage forms have been accepted:

Ampules Luminal-Sodium (Powder), 5 grains.
Capsules Luminal-Sodium, 5 grains.
Luminal-Sodium Tablets, ¼ grain.
Luminal-Sodium Tablets, ½ grain.

LIVER EXTRACT NO. 343 (See New and Nonofficial Remedies, 1932, p. 248).

The following dosage form has been been accepted:

Liver Extract No. 343, 110 Gm. bottle.

PRELIMINARY REPORTS OF THE COUNCIL

The Council has authorized publication of the following report.

W. A. Puckner, Secretary.

"NIRVANOL"

"Nirvanol" (Chemische Fabrik Von Heyden A.-G., Germany: Heyden Chemical Company, New York, distributor) is stated to be phenylethylhydantoin and is marketed in the form of tablets stated to contain 0.3 Gm. of phenylethylhydantoin and in the form of a solution in 4 cc. ampules containing 0.5 Gm. of the sodium salt of phenylethylhydantoin in 4 cc. of water. On request of the Council the American distributor obtained from the German manufacturer a statement of tests proposed for the identification of the product and transmitted it to the Council. The Heyden Chemical Company states that it is supplying the product to physicians and hospitals ordering it but is making no active propaganda for its sale.

The Council took up the consideration of "Nirvanol" at the request of the editor of The Journal, who asked that a preliminary report be prepared, to be published in the same issue of The Journal as the paper by T. Duckett Jones and John Lesh Jacobs (The Treatment of Obstinate Chorea with Nirvanol, this issue, p. 18). Nirvanol was introduced as an hypnotic but appears to have fallen into disuse for that purpose because of the rash that is commonly induced. The present report is concerned with its use in the treatment of chorea. It is almost trite to say that early clinical reports of a product are almost invariably more favorable than later reports, and the literature concerning Nirvanol seems to follow the rule. At any rate, Poynton and Schlesinger (*Lancet* **2**:267 [Aug. 10] 1929) write: "A new method of treating chorea with a preparation called nirvanol has recently had a fairly wide trial in Germany. In most clinics where the method has been used it has met with such constant success that it continues to be employed in severe and obstinate cases." In support of this statement they cite the favorable reports of Roeder (1919?), Rietschel, Hester, Husler, Matzdorff (1926), Huber, Schmal (1925) and Keller. They mention only two—Bendix, Buttner—who report that it has no advantage over any other form of treatment of chorea.

Schmal (*Deutsche med. Wchnschr.* **51**:1439 [Aug. 28] 1925) states that Frieda Roeder (1919?) was the first to report on the effect of Nirvanol in chorea. She administered Nirvanol in doses of from 0.3 to 0.45 Gm. during two days to each of two children. One had fever and rash on the ninth day and the other on the twelfth day. The chorea was relieved in one, and the other improved. Schmal treated three cases. The result was brilliant in one case, satisfactory in one, and one failed to improve. He states that the hypnotic action, which may extend even to stupor, is a great disadvantage, but he recommends it especially in severe cases of chorea.

De Rudder (*Klin. Wchnschr.* **5**:1522 [Aug. 13] 1926) states that the therapeutic effect of Nirvanol in chorea depends on the production of Nirvanol sickness—that is, exanthems, eventually fever, with puffiness of the face and mucous membrane, usually within twelve days, and showing a strong analogy to the incubation period of serum disease. He states that there is first an alkalosis, changing suddenly to acidosis, and to the latter he attributes the effects on the central nervous system resulting in temporary increase of choreic movements. He states that the quotient of Ca/inorganic phosphorus in serum sinks until the outbreak of the rash, so that it approaches the condition of a proanaphylactic tetany; that there is a high-grade eosinophilia at the time of the rash. He also mentions other analogies with serum disease and states that Nirvanol probably has the character of an antigen.

Matzdorff (*Deutsche med. Wchnschr.* **52**:528 [March 26] 1926) reports the treatment of two cases of chorea with Nirvanol. The first did very well indeed, but the second showed toxic symptoms, including stupor, without the appearance of rash, somewhat similar to that reported by Schmal. He believes the treatment is suited only for institutions. He states that the literature affords no conclusive evidence of any fatality due to Nirvanol, but that while it is effective it cannot be said to be harmless. Jones and Jacobs state that several deaths possibly, but not certainly, due to the drug have been reported. Matzdorff refers to one of these reports and dismisses the evidence, attributing the death to disease. Poynton and Schlesinger report favorable results with Nirvanol in the treatment of six cases. They state that it is effective, that there is an element of risk in its use, and that it may be considered unjustifiable to take such heroic measures to combat a self-limiting disease. They state, however, that it seems unwise to dismiss Nirvanol summarily on this plea alone. They state that the daily dose of 0.3 Gm. should not be exceeded and that if no rash appears by the fourteenth day, the method is useless and dangerous to proceed with, for which statement they quote Huber. East and Cullinan (*Lancet* **2**:190 [July 26] 1930) report that the rash occurred in only eight of their fifteen cases and that five did well without showing a rash. Twelve improved greatly; one improved moderately, and two showed no response. They state that one cannot foresee the reaction; that the symptoms if not dangerous are sometimes disturbing; that the attack is often cut short dramatically. They believe that the main justification for the use of Nirvanol would rest on a demonstration that abolition of chorea prevents cardiac disease, which remains to be proved; that we do not know that rheumatic infection is abolished, and that the results in two of their cases point to the opposite. They believe that Nirvanol should be used only in those cases which do not improve with ordinary treatment.

Pilcher and Gerstenberger (*Am. J. Dis. Child.* **40**:1239 [Dec.] 1930) report that the majority of children with chorea treated with Nirvanol reacted with fever and morbilliform rash; that following this reaction those with severe chorea usually improved promptly, but that the course of the disease in milder cases, and in those who did not react to the drug by fever or rash, was not appreciably altered, as a rule; (compare East and Cullinan); that the improvement usually occurred about the time the rash appeared, and that the temperature rose to as high as 105.4 F. There was pulmonary complication in one case, renal irritation and other symptoms in another. They call attention to Lengsfeld's report that patients treated with Nirvanol stayed in the hospital for a shorter time than others not treated with it; but Pilcher and Gerstenberger found no shorter stay in the hospital, though they admit that many factors determine this length of stay. They also state that Lengsfeld observed relapse of nine of twenty-three patients within two and a half years. Reichle (*Arch. Int. Med.* **49**:

219 [Feb.] 1932) compares the action of arsphenamine and cinchophen to Nirvanol sensitivity and says that the reaction to cinchophen is probably of the same type, the symptoms being strikingly allergic.

From this review of the literature, it would seem that the following conclusions are justified: (1) that a fairly large percentage of patients suffering with chorea are relieved by Nirvanol; (2) that there is no evidence that the relief of chorea by Nirvanol lessens the tendency to subsequent cardiac disease; (3) that there is no invariable relationship between the appearance of the various symptoms and the therapeutic effects. In other words, the therapeutic action is not the direct effect of any of the side actions, and that the therapeutic effects may occur in the absence of any one of these; (4) that a specific hypersensitiveness to Nirvanol has not been proved; (5) that the side actions are always disagreeable, sometimes alarming, and often positively dangerous, if not even fatal in a small proportion of cases; (6) that the treatment is too severe to justify its use except in those cases that do not yield readily to other treatment; (7) that Nirvanol should not be used in the treatment of chorea except in an institution where the patient is under close supervision.

The Council concluded that the treatment of chorea with "Nirvanol" is in the experimental stage, further investigation being necessary before a final statement of its value can be reached. Without, at this time, examining the claims regarding the identity of the product or considering the acceptability of the proprietary name, the Council voted to postpone action on "Nirvanol" to await the results of further investigation and authorized publication of this report.

REPORTS OF THE COUNCIL

The Council has authorized publication of the following report.

W. A. Puckner, Secretary.

TAR-ME-CINE NOT ACCEPTABLE FOR N. N. R.

Under the uninforming name "Tar-Me-Cine" the Tar-Me-Cine Laboratories, Inc., Waltham, Mass., market a preparation stated to have the following composition: "Chloral Hydrate 8 Drams. Resorcin 8 Drams. Tartaric Acid 10 Drams. 40 Grains. Phenol 10 Drams. 40 Minims. Glycerine 10 Drams. 40 Minims. Menthol 2 Drams. 55.4 Grains. Camphor 2 Drams. 55.4 Grains. Boric Acid 26 Drams. 40 Grains. Alcohol 282 Drams. 40 Minims. A suitable emollient vehicle.—Ad. Q.S. 128 Ounces." This "formula" is incomplete in that the identity of the ingredients which compose the "suitable emollient vehicle" (which may be the really important part of the mixture) is not declared. Furthermore, no statement of composition appears on the label of the preparation other than a declaration of the amount of alcohol and chloral hydrate, as required under the Food and Drugs Act.

According to the label, "Tar-Me-Cine" is "Used in the external treatment of chronic eczema and other skin diseases" and "has been successfully used in the treatment of Infantile Eczema, Poison Ivy, Salt Rheum, Acne and other kindred skin diseases."

As evidence for the usefulness of this complex mixture the Tar-Me-Cine Laboratories, Inc., sent a list of physicians "who have used Tar-Me-Cine, and found it to possess Therapeutic qualities, for the particular affliction for which they used it." Evidence was not presented, however, to indicate that this complex mixture of drugs is therapeutically superior to simpler preparations which physicians may prescribe and to which physicians should give preference in the interest of rational drug therapy.

"Tar-Me-Cine" is unacceptable for New and Nonofficial Remedies because the identity of the "suitable emollient vehicle" is not declared and because the identity and amounts of the potent ingredients are not declared on the label; because the recommendations on the label for use in specific diseases may lead to the ill advised use of the preparation by the laity; because no acceptable evidence is offered for the asserted efficacy of the mixture; because the name of the preparation is not descriptive of its composition, and because it is a complex and unscientific mixture.

Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

WHITE PEARL EGG NOODLE (FINE) AMERICA'S STANDARD

WHITE PEARL EGG NOODLE (WIDE) AMERICA'S STANDARD

Manufacturer.—Tharinger Macaroni Company, Milwaukee.

Description.—Egg noodles prepared from a mixture of durum patent flour, durum semolina and egg yolk; packed in wax-paper in cartons.

Manufacture.—The flour, semolina and egg yolk in definite proportions and with sufficient water are thoroughly mixed in a dough mixer, kneaded in a kneading machine, and then rolled and cut into noodle strips, which are dried in air currents to approximately 10 per cent moisture content and packed in wax-paper cartons.

Analysis (submitted by manufacturer).—

	per cent
Moisture	9.7
Ash	1.5
Salt (NaCl)	0.3
Lipoids	5.7
Protein (N × 6.25)	14.7
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	68.2
Lipoid phosphoric acid (P_2O_5)	0.130
Lipoid phosphoric acid (P_2O_5) (dry basis)	0.144
Artificial color	absent

Calories.—3.8 per gram; 108 per ounce.

Claims of Manufacturer.—These noodles are for all table uses for this type of product.

HEINER'S HUGE SLICED BREAD HEINER'S TWIN LOAF BREAD

Manufacturer.—Heiner's Bakery, Huntington, W. Va.

Description.—A white bread made by the sponge dough method (method described in The Journal, March 5, 1932, page 817); prepared from patent flour, water, yeast, a yeast food containing ammonium chloride, calcium sulphate, sodium chloride and potassium persulphate, salt, lard, sucrose and dry skim milk.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	35.9
Ash	0.8
Fat (ether extraction method)	0.9
Protein (N × 6.25)	9.3
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	52.8

Calories.—2.6 per gram; 74 per ounce.

Claims of Manufacturer.—A bread of good quality.

INTERNATIONAL FREE RUNNING SALT

Manufacturer.—International Salt Company, New York.

Description.—A table salt containing 1 per cent added calcium carbonate, which tends to preserve its "free running" quality.

Manufacture.—The salt is obtained by evaporation of salt brine made from rock salt deposits in the earth. Surface water is forced down into the rock salt deposits through deep wells. The brine so formed is pumped to the surface, treated with calcium hydroxide for purification, and stored in tanks to permit insoluble matter to settle out. The resultant clear brine, free from all precipitated matter, is conveyed to the evaporators. Two methods of evaporation are used: the "grainer," or open pan type, and the "vacuum," or closed pan type.

By the open pan evaporator method the brine is evaporated in long shallow tanks equipped with steam coils. As the water is evaporated, salt crystals form, settle to the bottom and are removed at regular intervals by mechanical raking devices. The size of the crystals depends on the speed of evaporation of the salt brine. The salt crystals are washed, freed from the brine by filtration, and kiln dried by passing through rotating heated dryers. The dried salt is screened to separate it into various sized grains. Salt of a definite and uniform granulation is admixed with 1 per cent calcium carbonate and automatically packed in paper cartons.

In the "vacuum" method, the brine is heated and evaporated under reduced pressure in closed vessels. The salt grains in the "vacuum" pans are perfect cubes: those in the open pans are flatter and are called "snowflake" salt.

Analysis (submitted by manufacturer).—

	per cent
Water insoluble material	0.00
Iron oxide (Fe_2O_3)	absent
Barium salts	absent
Calcium chloride ($CaCl_2$)	absent
Calcium sulphate ($CaSo_4$)	0.44
Magnesium chloride ($MgCl_2$)	0.06
Sodium chloride ($NaCl$)	98.50
Calcium carbonate (added) ($CaCO_3$)	1.00

Claims of Manufacturer.—International Free Running Salt is for all table uses of salt. The added calcium carbonate tends to preserve the "free running" qualities.

ASCO EVAPORATED MILK FARMDALE BRAND EVAPORATED MILK

Manufacturer.—American Stores Dairy Company, Dundee, Ill.

Description.—An unsweetened, sterilized evaporated milk.

Manufacture.—Only strictly sweet fresh milk of healthy herds and from sanitary farms regularly inspected by the company is used. On arrival at the plant, the milk is tested for flavor and acidity; milk of more than 0.18 per cent lactic acid is rejected. The milk is brought to a temperature of from 95 to 100 C., is concentrated in "vacuum pans" at 55 C. to a definite specific gravity, and homogenized by being forced through small apertures, which disperses the fat in fine globules which later will not separate out. The homogenized milk is standardized under laboratory supervision to conform to the United States Department of Agriculture standard for evaporated milk and automatically filled into cans through small openings which are automatically sealed. The sealed filled cans are brought to 100 C. and processed in a pressure cooker at 115 C. for fifteen minutes, after which they are quickly cooled.

The factory is maintained in a strictly sanitary condition. The equipment is cleaned daily with brushes and washing solution.

Analysis.—

	per cent
Moisture	73.8
Total solids	26.2
Ash	1.5
Fat	7.8
Protein (N × 6.38)	6.9
Lactose (by difference)	10.0

Calories.—1.4 per gram; 40 per ounce.

Micro-Organisms.—The product is sterile.

Claims of Manufacturer.—These brands of evaporated milk are for general baking, cooking and table purposes and for infant feeding. The mixture of equal parts of the evaporated milk and water is not below the legal standard for whole milk. The curds formed in the stomach are smaller, softer and more readily digestible than those from raw or pasteurized milk.

YACHT CLUB BRAND CORN SYRUP WITH CANE FLAVOR

(85 Per Cent Corn Syrup, 15 Per Cent Refiners' Syrup)

Packer.—D. B. Scully Syrup Company, Chicago.

Distributor.—Bemis, Hooper, Hays Company, Oshkosh, Wis.

Description.—A table syrup; a corn syrup base (85 per cent) with refiners' syrup (15 per cent).

Manufacture, Analysis, Calories and Claims of Manufacturer.—See these sections for Banner Blue Golden Syrup with Cane Flavor (THE JOURNAL, March 5, 1932, p. 817).

TRIPLE AAA BRAND PURE TOMATO JUICE

Manufacturer.—American Packing Corporation, Evansville, Ind. A wholly owned subsidiary of the Loudon Packing Company of Terre Haute, Ind.

Description.—Canned tomato juice; retains in large measure the vitamin content of the raw juice used. Contains a small amount of added salt.

Manufacture, Analysis, Calories, Vitamins and Comments.—See these sections for Loudon Brand Tomato Juice (THE JOURNAL, June 25, 1932, p. 2289).

KRE-MEL DESSERT (COFFEE FLAVOR)

A Mixture of Sugar (Dextrose and Sucrose), Corn Starch, Pure Coffee, Vanillin

Manufacturer.—Corn Products Refining Company, New York.

Description.—Mixture of dextrose, corn starch, sucrose; flavored with vanillin and coffee.

Analysis (submitted by manufacturer).—

	per cent
Moisture	7.0
Ash	1.2
Fat (ether extract)	1.1
Protein (N × 6.25)	1.1
*Dextrose	45.0
*Sucrose	20.0
*Starch	24.5
Caffeine less than	0.1
Crude fiber	0.0
Titratable acidity as HCl	0.03
Vanillin flavor	present

* Estimated from formula.

Calories.—3.7 per gram; 105 per ounce.

Claims of Manufacturer.—A dessert powder for the simple preparation of table desserts.

PORTOLA FILET OF SARDINES

(In Pure Olive Oil)

Manufacturer.—K. Hovden Company, Monterey, Calif.

Description.—Cooked, boneless, smoked Pilchard sardines (Clupea caeruleus, blue sardines) packed in olive oil in tins.

Manufacture.—Pilchard sardines harvested as described for the Portola Sardines (Pilchards) (THE JOURNAL, June 4, 1932, p. 1991) are used. As soon as the fish enter the plant, slices are cut off the body so as to eliminate the ribs and backbone. The meat slices are placed in wire baskets, submerged in a weak brine for fifteen minutes to extract the blood, dried, and smoked on wire trays from four to six hours. They are packed in cans and are steamed for four minutes standing upright and for ten minutes turned over to permit the draining off of excess water and oil. Olive oil is added and the cans are sealed and processed under the control of the California State Board of Health as to temperature and time.

Analysis, Calories and Claims of Manufacturer.—See these sections for Portola Sardines (Pilchards).

HELMS OLYMPIC WHEAT BREAD SLICED

(White and Whole Wheat Flours)

Manufacturer.—Helms Bakeries, Ltd., Los Angeles.

Description.—A bread prepared from white and whole wheat flours by the straight dough method (method described in THE JOURNAL, March 18, 1932, page 889); prepared from a mixture of white and whole wheat flours, yeast, a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, sweetened condensed skim milk, salt, lard, sucrose, invert sugar and water.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	34.0
Ash	2.0
Fat (Polenske-Grujic method, Leach, "Food Inspection and Analysis," ed. 4, p. 343)	2.6
Protein (N × 6.25)	11.2
Crude fiber	0.8
Carbohydrates other than crude fiber (by difference)	49.4

Calories.—2.7 per gram; 77 per ounce.

Claims of Manufacturer.—A good quality bread prepared from white and whole wheat flours.

SATURDAY, JULY 2, 1932

DIET AND HUMAN MILK NUTRIENTS

Recent studies in the growth and development of the child have emphasized anew the importance of having fuller knowledge of the physiologic rôle of the mother during the days of dependence of her baby. Indeed, few scientific problems in relation to maternal nutrition are of greater significance than those relating to the diet of the mother during the reproductive cycle and its subsequent effect on both mother and child. The knowledge that proper prenatal care and adequate maternal diet are effective factors in the postnatal development of the child shows the necessity of close cooperation between the obstetrician and the pediatrician.

The Journal[1] has emphasized that the human mother is subject to the influence of her own diet, which may be reflected to some extent in the composition of her milk. Shukers, Macy, Donelson, Nims and Hunscher[2] point out that it is acknowledged generally that the proper kind and amount of food are essential to the mother during pregnancy and lactation if she is to maintain good health and at the same time nourish her baby properly before and after birth. Medical literature is, nevertheless, practically barren of any extended studies on the effect of diet on human reproduction, and the feeding of women during this crucial period still remains largely empirical. In another report[3] these authors have reemphasized the fact that experimental work to demonstrate the precursors of milk constituents and factors determining the metabolic requirements for lactation has been done chiefly on mammals other than man and especially on the cow and the goat. Though the results with these animals are significant in indicating the general relationships, they cannot be expected to show the specific demands of woman. There is a possibility that the digestive processes of the ruminant and of man, as well as the synthetic capacity, may differ.

Extensive and timely studies on maternal nutrition are being carried forward on women in the Research Laboratory of the Children's Fund of Michigan, in Detroit, under the direction of Dr. Icie G. Macy. It has been observed that lactation increases the food demands approximately 60 per cent over and above those of pregnancy. The self chosen diets and the nutritive requirements of three women during sixty weeks of intensive lactation have been observed with especial reference to the intake of calories, proteins, fat, carbohydrate, calcium and phosphorus in the food and the outgo of these substances in the milk secreted. These women produced daily an average of 1,419, 2,366 and 3,134 cc. of milk. Since current regimens recommended for lactating women are empirical, it seems pertinent to consider the quantity of nutrients actually utilized in the secretion of such quantities of milk. When the necessary ingredients for milk synthesis are lacking in the daily food, the mother may decrease her milk output, secrete milk deficient in these constituents, or draw them from her own tissues. A marked deficiency of dietary proteins, fat or carbohydrate is usually associated with a prompt drop in milk volume; inadequate vitamin may result in a vitamin-deficient milk; while an insufficient mineral intake results in a drain on the maternal reserves. The Children's Fund investigators further state that intensive lactation is often marked by negative calcium and phosphorus balances but that there is obviously a limit to the amount of material a woman can lose from her tissues without some impairment of her body and a diminution in the nutritive value of her milk.

Macy and her co-workers point out that, under ordinary conditions, milk volume is the chief determinant of the total output of milk calories; therefore milk volume becomes a factor of moment in planning diets for lactating women. The food fuel of breast milk is derived from the cleavage products of the fats, carbohydrates and proteins of either ingested food or maternal tissue. The Detroit investigators show that women who ingested daily dietaries whose percentage distribution of calories between proteins, fats and carbohydrates was in the ratio of 15:37:48 and with caloric values of 4,300, 4,600 and 3,800 secreted milk containing 2,100, 1,500 and 1,120 calories, respectively; thus there were left approximately 2,000, 3,000 and 2,600 calories daily for maintenance, provided the human mother is 90 per cent efficient in the transformation of food energy into milk energy. These observations are in accord with the advice given by Rose,[4] who suggests that in planning a dietary for the lactating woman an allowance equal to 10 per cent of the caloric output in milk should be made for the dissipation of energy in the physiologic processes of milk secretion. They are not, however in agreement with those who follow the dictum of practices indicated in the dairy industry, and advise an extremely generous supply of two food calories for each breast milk calory beyond maintenance requirements. Calory overfeeding has not been demonstrated to be advantageous either to the cow or to woman and differences in species such as exist between the ruminant cow and woman have to be considered in the physiologic utilization of food calories in the secretion of milk and in the appraisal of lactation requirements.

[3] Shukers, Carroll F.; Macy, Icie G.; Donelson, Eva; Nims, Betty, and Hunscher, Helen A.: A Quantitative Study of the Maternal Dietary with Respect to the Nutrients Secreted into Breast Milk, J. Nutrition 5:127 (March) 1932.

[4] Rose, Mary S.: Feeding the Family, ed. 3, New York, Macmillan Company, 1929.

Hoobler[5] has demonstrated that the provision of an adequate protein intake during lactation is important since it has been shown that milk protein is ultimately derived from food protein and that the level of dietary protein affects the quantity of milk secreted and, within limits, its composition. The milk proteins are derived from the free amino-acids of the blood. Macy and her associates point out that the quantity and quality of the amino-acids in the circulating blood are changed by diet, by the varying nitrogen demand of the tissues, and by the supply of nonprotein calories. These changes have a marked influence on milk secretion. In the words of the authors, "because of the multiplicity of determinate influences it becomes difficult to set a physiological minimum for any body function and, indeed, it is impossible to state a quantitative protein requirement for complicated physiological functions such as those involved in lactation superimposed on maintenance."

One cannot review these studies on maternal nutrition without being impressed with the urgent need for more comprehensive observations on women and a closer scrutiny of the present empirical dietary standards for human reproduction. The importance of the problem justifies a more thorough study of the nutritional needs of women.

THE MEASUREMENT OF PHYSICAL GROWTH

One naturally thinks of the observation and measurements of a large number of persons at different ages and under different conditions as a simple way of securing useful information regarding growth. The investigator in this field is at once confronted with a practical difficulty in deciding how the crucial measurements shall be made. The procedure that promptly suggests itself, of securing data on the body weight, is far from a satisfactory way of estimating changes in size or development. There are changes in stature, muscular development, body proportions and so on that may be quite as significant as gains in weight; indeed, they may occur independent of the body weight. If there is such a condition as a "normal build" of the body, it may betray itself only by measurements that are not necessarily related to the weight. Consequently, attempts have been made to introduce other estimates into the study of growth. Height and girth have been measured. "Sitting height" was used by Pirquet to establish his "index of nutrition," or body build.

Zook[1] has pointed out that physical growth presents two aspects, the external and the internal. The external aspect is recognized as an increase in size or volume. The internal aspect consists in the many vital changes taking place within the body, such as the increase in the size of the heart and arteries and the percentage of muscle and bone. He argues that, since the human body and its segments are three dimensional, methods of measurement must be adopted which express the relations of these segments in units of volume. Accordingly, Zook has devised a method, at the University of Chicago, based on the time-honored principle of Archimedes: "The volume of water displaced by a body submerged is equal to the volume of the body," which is self evident. The ingenious apparatus of Zook records the volume not only of the body as a whole but also of its segments. Detailed measurements were thereby made on a large number of boys from 5 to 19 years of age, so that norms for each age group were secured. By measuring a well nourished group from the Laboratory Schools and a poorly nourished group from the University Settlement, it was possible to point out detailed differences in the groups. The cranium and the foot are the only segments that are practically equal in volume in the settlement and university groups. These segments are a larger percentage of the total body in the settlement group than in the university group. The settlement group is much lower than the university group in volume of all other segments, the greatest difference being found in the trunk. In these segments the two groups are about equal when the volume of these segments has been reduced to the percentage of the total volume. The use of his new method has enabled Zook to show the growth lag in late childhood and the adolescent spurt that follows for the body as a whole and for all the segments with the exception of the cranium and the foot. Of the three major segments, the leg is first to reach the low level and start the adolescent spurt at about 10 years of age, increasing to 12 and remaining high until after 16. The head segment begins its increase at about 11 years of age, increasing to 13 and dropping rapidly thereafter. The trunk begins its increase at about 12 and continues to increase until about 16; then it drops rapidly.

The significance of this new mode of examination is evaluated by its author as follows: It opens up an entirely new field by presenting a new method of studying physical growth. It makes possible the location of lags and spurts in growth for each of the segments in an individual or for a whole group. The chief value of the method will probably come when measurements have been made on the same subjects throughout their periods of growth. Although the method is of unquestionable value as a research device in physical growth, Zook believes it to be of great usefulness in school health work and other fields of education, such as swimming instruction. The measurement can be completed in about eight minutes. A comparison of the graphs made on the same subject at different times will show where and how extensive have been the changes in volume between the time of the two measurements. The study is significant also, Zook adds, in that it has shown the invalidity of formulas for body volume. Since the present method gives body volume accurately, any further need of such formulas is entirely eliminated. The specific gravity of the whole body should be significant to swimming instructors in locating natural difficulties in learning to swim. It may also have contributions to make in locating the onset of puberty or other physical changes.

[1] Zook, D. E.: The Physical Growth of Boys, Am. J. Dis. Child. **43**: 1347 (May) 1932.

It is not generally known that during the World War Bean,[2] working with the American Red Cross to provide more balanced artificial limbs for disabled soldiers, used water displacement to obtain the volume of the artificial limb by submerging the corresponding whole limb in water and measuring the water displaced. The specific gravity was determined, approximately, by finding the specific gravity of the limb that had been amputated. Thus having the desired volume and the specific gravity, an artificial limb could be made the same size and weight as the corresponding whole limb, restoring the symmetry and balance of the whole body as they were before the loss of the limb.

TILTON FOUND GUILTY

On June 16, Lester Tilton, notorious and aggressive promoter of a nostrum for cancer, was found guilty of conspiracy to violate the medical practice act of the state of Illinois. Similar verdicts were also brought by the jury against two co-defendants who aided Tilton in his quackery—Harry de Joannis, a promoter, and Joseph Duffy, a licensed physician. Tilton and de Joannis face a penitentiary term of from one to five years and the payment of a fine of $2,000. The jury recommended that some leniency be shown Duffy because of his comparative youth—a term of one day to one year in the county jail.

Tilton's activities have long been a stench and a disgrace to the Middle West. Originally from Clinton, Iowa, Tilton came, a year or two ago, to Chicago, doubtless deciding that Illinois offered a lush field. With the personnel that composed the Department of Registration and Education of the State of Illinois some years ago, Tilton's judgment might have been good. Fortunately for the public health, there was a change in this personnel; more recently, aggressive action has been taken by that department against those who are violating the medical practice act of the state of Illinois.

Tilton's "cancer cure," like practically every other humbug of the type, is an escharotic with a zinc salt as the active ingredient in a base of peat as the "mystery" element. Tilton's fake was dealt with by the Bureau of Investigation in an article that appeared in The Journal, June 7, 1930, and his methods and activities were described in detail at that time. Tilton has always worked the religious angle and has been particularly successful in interesting well meaning but technically untrained members of the Roman Catholic Church in supporting his schemes. At the time of The Journal's previous article, it was brought out that Tilton had worked through the nuns of an order in Wisconsin. More recently Tilton, with the aid of promoter de Joannis, was able to interest the nuns of the Felician Order in Chicago. The newspaper reports of the trial just completed brought out that they took in at the so-called clinic operated at the Felician convent, in the thirteen months of its operation, about $19,000, of which about $6,000 was paid to Tilton. Tilton testified that he had placed the "formulas" for his nostrum in escrow with a trust company to be turned over to the Felician nuns on his death. It was further disclosed in the course of the trial that Tilton and de Joannis had launched a scheme to incorporate the treatment for a million dollars, but this fell through following an investigation of the nostrum.

So rank did the scandal of the operation of this fake cancer cure in a nunnery become that Cardinal Mundelein requested his personal physician, Dr. Louis D. Moorhead, head of the medical committee of the Catholic archdiocese of Chicago and dean of the department of surgery at Loyola, to head a committee of physicians to investigate the convent clinic. Following this investigation, the cardinal ordered the clinic closed.

The testimony during the trial bore a striking resemblance to the testimony given at the Baker "cancer cure" libel suit of some weeks ago. In fact, the story of all such "cancer cure" fakes has a ghastly sameness. People with superficial benign growths or blemishes, which they believe to be cancer, go to these fakers; the blemishes are diagnosed cancer and are eaten out with escharotics; the victims suffer excruciatingly while it is being done but finally go home disfigured but, of course, healthy—for they had never been anything else. The poor sufferers from what is really cancer, many of whom have impoverished themselves or their loved ones to take the fake treatment, end up in the graveyard.

Owing to the complexities of American jurisprudence, which on occasion seems peculiarly to favor the manipulations of the criminal and to penalize the public, it is by no means certain as yet that Tilton will serve the sentence that has been pronounced. Nevertheless the state of Illinois is to be congratulated on the valiant fight it has made to protect its citizens against this heartless form of quackery. Particular credit belongs to Assistant State's Attorney Charles A. Bellows and to Judd E. Edwards, chief inspector of the Department of Registration and Education of the State of Illinois, for the work they have done in this case against unbelievable difficulties and malignant influences. Drs. Max Cutler, Francis Carter Wood, James P. Simonds, and other physicians deserve appreciation for giving of their time and effort to aid the state in this work.

Current Comment

RECIPROCAL IMMUNOLOGIC RELATIONSHIPS

The apparently spontaneous appearance of antipneumococcus immunity in growing rats is the latest form of Friedberger's "maturation panimmunity" to be challenged by American investigators. Dr. Victor Ross[1] of the department of health of New York City found that mice and young rats are nearly equal in susceptibility to experimental inoculation with pneumococci but that adult rats, grown with no known contact with these micro-organisms, may in extreme cases resist a million times the youthful minimum lethal dose for this animal species. This apparently normal adult immunity to pneumococcus, however, is not the same for all types of this infection. It appears earliest and is most effective against type II pneumococcus, is less prompt in its appearance and much less effective against type III, and is not demonstrable with type I. Dr. Ross interprets his observation as evidence of the presence in the normal intestinal tract of rats of saprophytic micro-organisms antigenically related to the type II and type III pneumococcus. In support of this hypothesis he quotes Sugg and Neill's[2] demonstration of the reciprocal immunologic relationship between type II pneumococcus and certain yeasts (Saccharomyces cerevisiae), and Avery, Heidelberger and Goebel's[3] demonstration of a potentially antigenic polysaccharide common to type II pneumococcus and the Friedländer bacillus. While at present Dr. Ross's theory of reciprocal environmental immunization must be regarded as little more than a plausible explanation of his results, his theory is nevertheless in line with the current tendency to seek other than specific infectious factors to account for adult immunity to poliomyelitis, scarlet fever, diphtheria, tuberculosis and certain other specific infections. Zozaya's[4] description of a common antigenic factor in meningococcus and certain putrefactive bacteria, and the subantigenic lipoids[5] now known to be common to certain pathogenic bacteria and certain animal tissues which may serve as food, are other examples of the newer knowledge of such conceivably important heterophile relationships.

N. A. COBB, NEMATOLOGY AND MEDICINE

Probably few persons, well informed in the subject, will deny that Dr. N. A. Cobb of the U. S. Department of Agriculture, whose death has just occurred, was the leading specialist of this country and perhaps of the world in the zoological group known somewhat incorrectly as the "free-living nematodes." It has been estimated that by their infestation of live stock the nematodes cause a loss of one hundred million dollars annually. In his address before the American Society of Parasitologists in January, 1931, and in subsequent papers, Cobb castigated his zoological colleagues for their lack of interest in the nemas and he flayed the authors of textbooks for not keeping up to the times in laying before their audiences the enticing anatomic and biologic details of his specialty. The question arises whether a correspondingly brilliant specialist in mammalogy, ornithology, ichthyology or many other zoological "ologies" could not present equally valid arguments for his field. College and high school zoology resemble the changing "fashions." Zoological trends are established by the professors of certain universities which by more or less general consent are accepted as centers for training teachers, and the zoological tendencies of these professors radiate through their graduates to the colleges and high schools. Had Cobb, with his inspiring enthusiasm, been head professor of zoology at any one of, say, ten leading universities, nematology would become more fashionable than it is today in college and high school courses. Unfortunately, the field is so large that the teacher of beginners can select only a small portion of the vast field of zoology to pass on to his pupils. The "survey" courses in general biology and general zoology can touch only a few of the high spots of the subject. Much the same situations exist in medicine. It is not unnatural that the average instructor follows the path of least resistance and is influenced more by what he has been taught than by what is published in the recent special journals. Cobb's argument in reference to nemas versus echinoderms seems, from the medical sidelines, well founded. His address was in reality another protest against the intellectual miser who seeks knowledge for the sake of knowledge instead of for the good it will do.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 10:45 to 10:50 a. m. over Station WBBM (770 kilocycles, or 389.4 meters). The Columbia chain program has been discontinued for the present.

The program for the week is as follows:

July 4. Holiday; no broadcast.
July 6. Keeping the Baby Well.

There is also a fifteen minute health talk sponsored by the Association on Saturday morning from 10:45 to 11 over Station WBBM, Chicago.

The program for the week is as follows:

July 9. What Is Acidosis?

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Portrait of Dr. Robertson.—The Barbour County Medical Society was presented with a portrait of the late Dr. James W. Robertson, Clayton, June 7. Dr. Robertson was president of the society from 1926 to 1928. Dr. George O. Wallace, Bakerhill, presented the portrait, and Dr. James Reid, Clayton, president of the society, presided. The speaker was Dr. Thurston A. Warren, Clayton.

Society News.—At the meeting of the Northeastern Division of the Alabama State Medical Association, June 3, at Scottsboro, the speakers included Drs. Amos C. Gipson, Gadsden, on "Cultivating the Child's Appetite"; Edwin V. Caldwell, Huntsville, "Diagnosis and Treatment of Fractures of the Pelvis"; German P. Haymore, Chattanooga, Tenn., "Subacute Bacterial Endocarditis"; Seale Harris, Birmingham, "Epilepsy, Associated with Hyperinsulinism: Its Control by Diet," and Marion R. Moorman, Huntsville, "Otomycosis." Dr. Hugh Boyd, Scottsboro, president of the Jackson County Medical Society, presented a case report on Rocky Mountain spotted fever.

CALIFORNIA

Immunization Programs.—Nine physicians of Placer County, cooperating with the county health officer and the state department of health, recently provided immunization against diphtheria to 1,237 children in one week. In Madera County, 2,000 children have been vaccinated against smallpox since March 23. Madera County is sparsely settled and the schools are widely separated.

State Medical Meeting.—Dr. Joseph M. King, Los Angeles, was installed as president of the California Medical Association at its recent annual meeting in Pasadena. Dr. George G. Reinle, Oakland, was made president-elect, and Dr. Emma W. Pope, San Francisco, reelected secretary. Del Monte was chosen as the place for the next annual session, April 24-27, 1933, with headquarters at the Del Monte Hotel. Speakers at the recent meeting included Drs. Samuel A. Levine, Boston, on "Clinical Aspects of Coronary Disease"; Fred H. Albee, New York, "Treatment of Fracture of the Hip"; George K. Rhodes, San Francisco, and Donald C. Collins, Rochester, Minn., "Perforated Peptic Ulcer"; Karl A. Menninger, Kansas City, "Psychoanalytic Aspects of Suicide"; Harvey T. Olsan, Los Angeles, "Syphilitic Pneumonia"; Albert L. Chaney, Ph.D., Los Angeles, "Purity of Nitrous Oxide—with Especial Reference to Nitrogen Content"; John F. Kessel, Ph.D., Los Angeles, "Bacillary Dysentery—Laboratory Observations and Bacteriophage Therapy"; Karl F. Meyer, Ph.D., San Francisco, "Principles of Prophylaxis Against Typhoid Fever, Whooping Cough, Scarlet Fever and Smallpox," and Daniel Beecher, deputy district attorney, Los Angeles, "The Physician as an Expert Witness—His Qualifications, Duties and Limitations, with Suggestions for Relief of Present Status of Expert Witnesses." A special exhibition included sixty-one books and manuscripts relating to medical knowledge in Tudor England.

COLORADO

Survey of Housing Conditions.—With a reduction in infant and maternal mortality as one of its objectives, a survey of housing conditions in the so-called slum districts of Denver was made in August, 1931. When the compilation of data was complete, the building inspectors were requested to pass on buildings that were not considered habitable. Condemnation proceedings then were instituted. Fifty-seven houses, eleven stores and five garages were among the buildings demolished. The wrecking was done by the city at no expense to the owner. In many cases it was necessary to arrange for the housing of the occupants at city expense. When it was possible to place property in habitable condition, a definite time limit was set for the improvement. Among the five districts surveyed, the highest infant mortality rate found was 250 per thousand live births. Although the statistical study has not been completed, efforts thus far have been directed to showing the advisability of demolishing the so-called slum district.

DISTRICT OF COLUMBIA

Society News.—The Medical Society of the District of Columbia has authorized its committee on civic health to provide volunteer physicians to aid in a temporary clinic at the so-called Bonus Army camp. Dr. Donald S. Knowlton is director of the clinic. The action was taken as a measure to protect public health.

Hospital Discontinues Undergraduate School.—The board of directors of the Children's Hospital, Washington, put into effect, April 1, a new plan which stops the admission of new students in its training school and which accepts only graduate and affiliate students for nursing service. Students already in the school will be graduated on satisfactory completion of their course.

ILLINOIS

Fifty Years of Practice.—An open-air dinner was given by the Randolph County Medical Society, June 17, in honor of Drs. James W. Weir, Sparta, and William A. James, Chester, to celebrate their completion of fifty years in the practice of medicine. Speakers included Dr. William K. McIntyre, St. Louis, on "Pruritus Ani."

Society News.—A symposium on cancer was conducted before the La Salle County Medical Society in Ottawa, June 21, by Drs. Peter A. Nelson, Jr., Joseph E. F. Laibe and Herbert E. Schmitz, all of Chicago.——Dr. Samuel M. Feinberg, Chicago, addressed the Carroll County Medical Society at Savanna, June 17, on "Respiratory Allergy."

Chicago

Society News.—The officers of the Chicago Academy of Criminology for the coming year are: president, Edwin H. Sutherland, Ph.D., department of sociology, University of Chicago; vice presidents, Dr. Ludvig Hektoen, director, John McCormick Institute for Infectious Diseases; Dr. Paul L. Schroeder, director, Institute for Juvenile Research, and Arthur J. Todd, Ph.D., department of sociology, Northwestern University, and secretary, Dr. Meyer Solomon, department of neurology, Northwestern University Medical School.

Portrait of Dr. Bensley.—Presentation of a portrait of Dr. Robert R. Bensley was made to the University of Chicago, June 14, when a group of Dr. Bensley's students, colleagues and other friends gathered at a dinner given in his honor. Dr. Bensley is professor of anatomy in the Division of Biological Sciences at the university and has been a member of the department since 1901. The speakers included Dr. Gotthelf Carl Huber, professor of anatomy, University of Michigan Medical School, Ann Arbor, who spoke on behalf of the science of anatomy; Julius Stieglitz, Ph.D., chairman, department of chemistry, representing the faculty of the university, and Charles Judson Herrick, Sc.D. Richard E. Scammon, Ph.D., formerly dean of the division and now professor of anatomy at the University of Minnesota, was among the guests. The portrait was painted by Mr. Edmund Giesbert of the art department of the University of Chicago.

Maxwell Street Dispensary Under New Plan.—Beginning July 1, the Maxwell Street Dispensary of the Chicago Lying-In Hospital will be operated as a neighborhood maternity clinic, for a period of ten years. The dispensary will be known as the Chicago Maternity Center, and the lying-in hospital will continue to work in affiliation with it. The hospital had its beginning in the dispensary thirty-seven years ago, when Dr. Joseph B. De Lee, who is in charge of the hospital, founded it in four rooms of a tenement at Maxwell Street and Newberry Avenue. Since then the dispensary work has been carried on continuously. Hospital care is provided for homeless expectant mothers, but most of the work of the staff is done in the homes of the poor. Free nursing and medical service are furnished. The change in management was necessary because of lack of funds. As the closing of the institution would deprive women of the district of the proper care, it is hoped that sufficient funds will be procured to assure its continued operation. Dr. De Lee will continue as chief of the consulting staff.

Society for Personality Study.—Dr. Meyer Solomon, associate in neurology, Northwestern University Medical School, was elected president of the Chicago Society for Personality Study, organized May 25. Other officers elected are Ernest W. Burgess, Ph.D., professor of sociology, University of Chicago, vice president, and Dr. Paul L. Schroeder, professor and head of the department of criminology, University of Illinois College of Medicine, secretary. Charter members of the society include Harvey Carr, Ph.D., professor of psychology, University of Chicago; Dr. John Favill, associate clinical professor of neurology, Rush Medical College, and Robert H. Gault, Ph.D., professor of psychology, Northwestern University. It is the intention of the society to study human behavior and personality from all angles. Monthly meetings will bring together psychiatrists, psychologists, sociologists, anthropologists, educators, physiologists, biochemists, political scientists, criminologists and others concerned with advancement of the knowledge of personality. Problems to be studied will comprehend family situations, incompatibility, delinquency, the alcohol and drug habits, cerebral fatigue, constitutional make-up, and others. Membership will be limited to 100.

INDIANA

Dr. Barnhill Honored.—Resolutions of appreciation and a gold watch were presented to Dr. John F. Barnhill, Miami Beach, Fla., at the close of a graduate course on the eye, ear, nose and throat, which he conducted at Indiana University School of Medicine recently with the assistance of members of the faculty. Dr. Barnhill has been professor of surgery of the head at Indiana University School of Medicine for many years. He was secretary of the Section on the Eye and Ear of the American Medical Association from 1901 to 1903, and chairman in 1904.

Dr. Gatch Appointed Dean of Indiana University.—Dr. Willis D. Gatch, professor of surgery in the Indiana University School of Medicine, Indianapolis, since 1911, has been appointed dean of the school to succeed Dr. Charles P. Emerson. Dr. Gatch has been acting dean of the school since Dr. Emerson's departure last fall to engage in the inspection of missions in the Far East on behalf of the Rockefeller Foundation. He was graduated from Indiana University in 1901 and received his degree of doctor of medicine from Johns Hopkins University School of Medicine in 1907. Dr. Emerson, who will return soon, has been elected research professor in the medical school. He has been professor of medicine and dean of the school since 1911.

LOUISIANA

Bill Introduced.—H. 737 proposes to prohibit the issuance of marriage licenses unless both parties to the proposed marriages present certificates from a coroner stating that they are free from syphilis. It is to be the duty of coroners to take samples of blood from both parties to the proposed marriages and to mail such samples to the state board of health for Wassermann tests. If the reactions to the tests are negative, coroners are to issue medical certificates, which authorize the proper officials to issue marriage licenses.

Health at New Orleans.—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended June 18, indicate that the highest mortality rate (15) appears for New Orleans and the rate for the group of cities as a whole, 10.1. The mortality rate for the corresponding period last year for New Orleans was 14.1 and for the group of cities, 10.5. The annual rate for eighty-five cities for the twenty-four weeks of 1932 was 12.1, as against a rate of 13 for the corresponding period of 1931. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

MARYLAND

Lectures for Midwives.—Lectures for midwives and applicants for licenses to practice the profession were started at the Baltimore City Health Department, June 7, under the auspices of the state department of health. They will be given by Dr. Max Alexander Novey, chief of the obstetric division of city department, and Dr. William H. F. Warthen, chief of the bureau of child welfare.

Full Time Health Positions.—Dr. William J. French, New York, has been appointed full time health officer of Howard County, with headquarters at Ellicott City, and Dr. Robert H. Johnson, Brookhaven, Miss., full time health officer of Somerset County, with headquarters at Princess Anne. With the installation of full time health service in these counties, there are but two counties remaining in the state with part time health service (THE JOURNAL, Oct. 10, 1931, p. 1082). At present, 94.3 per cent of the rural population of Maryland is covered by full time health service and 97.1 per cent of the state, including Baltimore. Dr. French was director of the Child Welfare Commission of Delaware and the Fargo Child Health Demonstration of the Commonwealth Fund. Dr. Johnson has been director of the Lincoln County Department of Health, cooperating with the Mississippi State Board of Health.

Consultants to City Health Department.—The following physicians were appointed to serve as consultants to the Baltimore Health Department, May 26, according to Baltimore *Health News:*

Dr. Arthur G. Barrett, president, West Baltimore Medical Association.
Dr. Thomas S. Cullen, Maryland State Board of Health.
Dr. Allen W. Freeman, professor of public health administration, Johns Hopkins School of Hygiene and Public Health.
Dr. Wade Hampton Frost, dean, Johns Hopkins School of Hygiene and Public Health.
Dr. Andrew C. Gillis, professor of neurology, University of Maryland School of Medicine.
Dr. George Milton Linthicum, chairman, public health committee, Baltimore City Medical Society.
Dr. Arthur J. Lomas, superintendent, University of Maryland Hospital.
Dr. Maurice C. Pincoffs, professor of medicine, University of Maryland School of Medicine.
Dr. Robert H. Riley, director, Maryland State Department of Health.
Dr. James M. H. Rowland, dean, University of Maryland School of Medicine.
Dr. George Walker, board of supervisors of city charities.
Dr. William H. Welch, director emeritus, Johns Hopkins School of Hygiene and Public Health.
Dr. Samuel Wolman, president, Maryland Tuberculosis Association.

The appointment of this group in this capacity was one of the major recommendations of Dr. Joseph W. Mountin, following his recent survey of health and hospitals of Baltimore.

MASSACHUSETTS

George Strong Derby Fund.—Contributions to a permanent fund to be established at the Massachusetts Eye and Ear Infirmary, Boston, in memory of Dr. George Strong Derby, are being collected. Dr. Derby, until his death, Dec. 12, 1931, was Williams professor of ophthalmology at Harvard University Medical School. The income from the fund will be devoted to projects in which he was interested; at present, it will be used toward the salary of a social worker engaged in the care of patients suffering from glaucoma. Other purposes will be determined from time to time as recommended by the staff of the infirmary and authorized by the board of managers.

MICHIGAN

Society News.—The unveiling of a portrait of Dr. James Decker Munson, for several years medical superintendent of the Traverse City State Hospital, took place, June 10, at a ceremony in the hospital. The portrait was presented by the Grand Traverse-Leelanau County Medical Society and the Traverse City State Hospital Nurses' Alumni Association.——The Kalamazoo Academy of Medicine was addressed, June 21, by Nathan Sinai, D.P.H., Ann Arbor, on "Economic Changes in Medicine," and Dr. John E. Gordon, Detroit, "Acute Infectious Diseases of the Central Nervous System."——Dr. George A. Kamperman, Detroit, addressed the Kent County Medical Society at Grand Rapids, May 26, on "Medical Aspects of Birth Control."——The Macomb County Medical Society heard a paper on "Preventive Medicine and Abortion," June 6, by Dr. Harold C. Mack, Detroit.

MINNESOTA

"Eye Specialist" Sentenced.—Elliott Wilkinson, one of a group of alleged fake "eye doctors" who swindled southern Minnesota residents out of several thousand dollars eight years ago, pleaded guilty to a charge of grand larceny in district court in New Ulm, and was sentenced by Judge A. B. Gislason to a term of one to five years in Stillwater Penitentiary, according to the St. Paul *Dispatch,* April 11. It was said that the charge was the outgrowth of an alleged fake eye operation performed on a woman in September, 1924. Wilkinson also pleaded guilty to a charge of attempted grand larceny in connection with another operation on a man the same year. The judge imposed a similar sentence and then suspended it. Wilkinson was one of the group of eyesight swindlers recently arrested in Texas and extradited to Minnesota. It is reported there are four felony warrants awaiting him in California, all in connection with asserted eyesight swindling operations. Authorities of other states reporting eyesight swindles may be interested in investigating Elliott Wilkinson's activities.

MISSOURI

Personal.—Dr. Joseph Erlanger, professor of physiology, Washington University School of Medicine, St. Louis, was recently given the degree of doctor of laws by the University of California.——Friends of Dr. William H. Allen, Rich Hill, recently held a gathering to observe the physician's eighty-second birthday. Dr. Allen has practiced medicine in Rich

Hill for fifty-seven years and is an honor member of the Bates County Medical Society.

Bulletin on Mental Hygiene.—The *Mental Hygiene Observer* appeared in April, published by the Missouri Society for Mental Hygiene. The officers of the recently reorganized group are Drs. Malcolm A. Bliss, St. Louis, honorary president; James Lewald, St. Louis, president; Emmett F. Hoctor, Farmington, vice president, and Mr. A. W. Jones, secretary. The activities of the organization included a survey of the insane in Missouri, in 1919, which was financed by the Rockefeller Foundation.

MONTANA

State Medical Meeting.—The fifty-fourth annual meeting of the Medical Association of Montana will be held at Miles City, July 13-14, under the presidency of Dr. John H. Garberson, Miles City. The program will include the following speakers:

Dr. Edward H. Cary, Dallas, Texas, President, American Medical Association, "Some Problems of the Modern Doctor."
Dr. John A. Evert, Glendive, "Boehler Treatment of Leg Fractures."
Dr. George E. Brown, Rochester, Minn., "Present Concepts of Hypertension."
Dr. John A. Wolfer, Chicago, "Gall Tract Disease: Surgical Indications."
Dr. Fred F. Attix, Lewistown, "Comments on Local Medical History for Permanent Record."
Dr. George J. McHeffey, Butte, "Oliver Wendell Holmes—Physician."
Dr. Archie L. Gleason, Great Falls, "Subacute and Chronic Pulmonary Lesions in Children."
Dr. Herbert H. James, Butte, "Late Treatment of Cancer of the Cervix with Radium."
Dr. Arthur R. Kintner, Missoula, "Fever of Unknown Origin."
Dr. Harold W. Dobbin, Missoula, "Foreign Body in the Heart."
Dr. Harold C. Joesting, Butte, "Advantage of Unsweetened Evaporated Milk for Infants."

NEW JERSEY

State Medical Election.—Dr. A. Haines Lippincott, Camden, was elected president of the Medical Society of New Jersey at the annual session in Atlantic City, June 17. Vice presidents are Drs. Frederic J. Quigley, Union City; Lancelot Ely, Somerville, and Marcus W. Newcomb, Browns Mills. Drs. John Bennett Morrison, Newark, and Elias J. Marsh, Paterson, were reelected secretary and treasurer, respectively.

License Revoked.—The license to practice medicine and surgery in the state of New Jersey of Dr. Samuel Dixon Mayhew, Wildwood, was recently revoked by the state board of medical examiners because of chronic inebriety.

Society News.—Dr. Leon S. Loizeaux, New York, addressed the Mercer County Medical Society, Trenton, May 11, on obstetric technic.——Drs. Grant Thornton and James Burns Amberson, Jr., New York, were the speakers at a meeting of the Morris County Medical Society, Morristown, May 19, on "Early Diagnosis of Tuberculosis" and "Clinical Course of Tuberculosis," respectively.——At a meeting of the Passaic County Medical Society, Passaic, May 12, Dr. Alfred Gordon, Philadelphia, spoke on "Psychoneuroses in Relation to General Medicine."

NEW YORK

Syracuse Alumni Meeting.—Dr. Edward N. Packard, Saranac Lake, was elected president of the Medical Alumni Association of Syracuse University at the annual meeting, June 2. Clinical conferences and demonstrations marked the reunion. Dr. Francis Carter Wood, New York, was among the speakers at the annual banquet, presenting an address on "The Cancer Situation and the Medical Profession." It was announced that Dr. Albert G. Swift has been appointed professor of surgery to succeed Dr. Edward S. Van Duyn.

Symposium at Saranac Lake.—A medical symposium was held at the National Variety Artists Sanatorium at Saranac Lake, May 28-30, for students at the Trudeau Sanatorium. Among the physicians who participated were Drs. Pol N. Coryllos, New York, who spoke on "Chest Surgery in Tuberculosis"; Edward C. Reifenstein, Syracuse, "Acute Bacterial Endocarditis"; Lemuel Whittington Gorham, Albany, "Pathologic Significance of Cardiac Infarcts"; David H. Ballon, Montreal, "Carcinoma of the Esophagus" and Aaron Brown, New York, "Diagnosis and Treatment of Seasonal Hay Fever."

New York City

Changes at Long Island College.—Dr. Alfred C. Beck has been appointed professor of obstetrics and gynecology at Long Island College of Medicine to succeed the late Dr. John O. Polak. Edgar D. Congdon, who for the past five years has been in charge of the department of anatomy at the Medical School of Chulalankarana University, Bangkok, Siam, has been appointed professor of anatomy. A new division of preventive medicine and community health has been created within the department of medicine, with Dr. Alfred E. Shipley, associate professor of preventive medicine and hygiene, at its head.

Smuggling Uninspected Milk.—Wholesale smuggling of milk and cream into New York from uninspected sources has been reported by the health department. Within the past four months, the department has detailed 191 inspectors with special police authority, who with the aid of fifteen men assigned by the police department have patrolled ferries, bridges, tunnels and detraining points. They barred 25,000 pounds of milk products and destroyed 27,490 pounds of cream from the Middle West, according to the report. Permits of three wholesale dealers are said to have been revoked and action is pending against others. It was said that gangsters were recognized guarding the contraband trucks.

Honor Graduates.—Prizes for excellence of work were awarded to members of the graduating class at Cornell University Medical College at the annual commencement, June 3, as follows:

John Metcalfe Polk Memorial Prizes to students with highest standing—Harold Russell Meyers, Jr., Rudolf Friedhold Bachmann and Charles Kevork Bogoshian.

For efficiency in otology—Jesse Potter Eddy, Rudolf F. Bachmann.

William M. Polk Memorial Prizes in Gynecology—Robert Edward Rothenberg, Abbey David Seley and Henry Carnie Lawson.

Gustav Seeligman Prizes in Obstetrics—Marion Fairfield and Abbey David Seley.

Alfred Moritz Michaelis Prize for efficiency in general medicine—Raymond Gettinger.

For efficiency in neurology—Harold Russell Meyers, Jr.

Dr. Walter L. Niles, professor of clinical medicine at Cornell, delivered the graduating address.

NORTH CAROLINA

Personal.—Dr. Greene L. Rea has been appointed acting health officer of Charlotte, succeeding Dr. Wilbur A. McPhaul, who recently resigned to become health officer of Pensacola, Fla.

University News.—Eighteen students made up the first class graduated from Duke University School of Medicine, Durham, June 8. As a part of the exercises, the class planted ivy sent from the home of Sir William Osler, in Oxford, England, at the entrance to the medical school. Dr. William Sydney Thayer, Baltimore, a former pupil of Osler, made an address at this ceremony and during the commencement season gave a clinic on cardiac disease at Duke Hospital.

Society News.—Dr. Thomas R. Brown, Baltimore, addressed the Eighth District Medical Society at its annual meeting in Greensboro, May 24, on "Medical and Surgical Treatment of Certain Diseases of the Digestive Tract." Among other speakers were Drs. Harry L. Johnson, Elkin, "Treatment of Acute Empyema"; Frederick C. Hubbard, North Wilkesboro, "Gunshot Wounds of the Abdomen" and Russell O. Lyday, Greensboro, "Indications for Conservative and Radical Surgery in Peptic Ulcer."

PENNSYLVANIA

Society News.—Drs. John B. Lownes and James L. Richards, Philadelphia, addressed the Schuylkill County Medical Society, Shenandoah, June 14, on gonorrhea.——A symposium on gastric and duodenal ulcer was presented at a joint meeting of the medical societies of Clearfield, Jefferson and Indiana counties, at the Crystal Springs Hunting Club, near Clearfield, June 23, by three members of the University of Pittsburgh School of Medicine. Dr. Roy R. Snowden discussed the subject from the point of view of the internist; Dr. George W. Grier, that of the roentgenologist, and Dr. Edwin P. Buchanan, that of the surgeon.

Annual Cancer Study Course.—The fourth annual course of study in cancer will be held in Lewistown, August 11, under the auspices of the commission on cancer of the Medical Society of the State of Pennsylvania. Drs. George P. Muller, Philadelphia, and Frederick B. Utley, Pittsburgh, will speak on the surgical and medical aspects of cancer, respectively. In the afternoon, clinics will be conducted by Drs. William Wayne Babcock, Philadelphia, on "Diseases of the Breast"; George E. Pfahler, Philadelphia, "Diseases of the Skin" and Dean Lewis, Baltimore, "Diseases of the Abdomen." During the afternoon also Dr. Byron H. Jackson, Scranton, will conduct a round table discussion and demonstration of roentgenograms. Drs. Charles Falkowsky, Jr., Scranton, Harold L. Foss, Danville, and Jonathan M. Wainwright, Scranton, will make addresses in the evening.

Philadelphia

Professor Donaldson Honored at Seventy-Five.—The volume of the *Journal of Comparative Neurology* beginning with the June issue is dedicated to Henry Herbert Donaldson, Ph.D., professor of neurology at the Wistar Institute of Anatomy and Biology, in honor of his seventy-fifth birthday, which occurred, May 12. Professor Donaldson has been associated with the institute since 1906. Previous to that time he was professor of neurology at the University of Chicago for fourteen years and also taught at Johns Hopkins and Clark universities. In 1895 he published a book on the growth of the brain and in 1915 the results of his studies of development in the rat. Dr. Donaldson was president of the American Association of Anatomists in 1916 and of the American Society of Naturalists in 1927.

Tumor Study Bureau Offers Slides.—The Central Bureau for the Study of Tumors, Lankenau Hospital, Philadelphia, announces that it has available a number of sets of microscopic slides. Each set contains 100 slides from 100 different tumors. Dr. Joseph McFarland, director of the bureau, has prepared a book of mimeographed notes in which the source of each tumor is given, its clinical course briefly summarized, the diagnosis and prognosis, and other explanations. The slides have numbers etched on them, are without labels and are unknowns until identified by reference to a number in the lid of the box. The collection, which is sold for $100 a set for the benefit of the bureau, is adapted to a variety of purposes, such as the self-instruction of resident hospital pathologists in oncology, examination of students and hospital residents, material for microprojection in the classroom, standards for comparison in making diagnosis of the rarer tumors, and raising the standard of work done in hospital laboratories by showing the technicians how satisfactorily prepared sections should look. As the material was used up in making the slides, they cannot be duplicated, the announcement says. Inquiries should be directed to the bureau, Lankenau Hospital, Philadelphia.

SOUTH CAROLINA

Faculty Changes.—At the annual commencement of the Medical College of the State of South Carolina, June 2, these faculty appointments were announced:

Dr. Francis G. Cain, assistant professor of gynecology.
Dr. Wythe M. Rhett, assistant professor of pediatrics.
Dr. Archibald Johnston Buist, Jr., assistant professor of gynecology.
Dr. Joseph I. Waring, lecturer in pediatrics.

Dr. Max William Hemingway of the graduating class was awarded the Ravenel cup for a thesis on "The Maternity Death Rate in South Carolina."

VIRGINIA

Graduate Courses Organized.—The first circuit for the graduate course in prenatal and postnatal care, which is being given under the auspices of the Medical Society of Virginia through a grant from the Commonwealth Fund (The Journal, June 4, p. 1999) was begun during the first week of June. It includes the medical societies of Nelson, Rockbridge, Albemarle and Augusta counties and the Lynchburg Academy of Medicine. Two-hour sessions will be held weekly for ten weeks under the direction of Dr. Maxwell E. Lapham, formerly of Philadelphia, who was recently appointed to carry out this extension of the state society's activities. Among the subjects covered are early diagnosis of pregnancy, prenatal examination, instructions to patients, preparation for and management of labor and delivery, care of new-born infants, postpartum complications and toxemias of pregnancy. A second circuit of five centers will be begun immediately after the conclusion of the present series in August.

WISCONSIN

District Meeting.—Dr. Morris Fishbein, Chicago, was the guest speaker at an evening meeting of the Sixth District Medical Society at Appleton, June 9, on "Present-Day Trends of Private Practice in the United States." At an afternoon session, demonstrations were presented on the following subjects: treatment of fractures, by Dr. Ralph M. Carter, Green Bay; heart disease, Dr. Newell C. Gilbert, Chicago; varicose veins and ulcers, Dr. Herman O. McPheeters, Minneapolis, and joint and back injuries, Dr. Harry E. Mock, Chicago. Counties in the sixth district are Brown, Kewaunee, Door, Outagamie, Winnebago and Fond du Lac.

Course in Pediatrics.—A course of lectures and clinics in the diseases and feeding of children will be offered to Wisconsin physicians, beginning July 11 and continuing six weeks, under the auspices of the Wisconsin State Medical Society, the University of Wisconsin Medical School and the University of Wisconsin Extension Division. Dr. Wayne A. Rupe, St. Louis, will be the instructor in the course, which will be given in Milwaukee, Waukesha, Racine, Kenosha and Burlington. Among the topics listed for study are newer methods of prevention and treatment of certain contagious diseases, breast feeding and artificial feeding, colic, diarrhea, infantile skin diseases, and treatment of pyelitis, enuresis, nephritis and nephrosis.

Society News.—The Brown-Kewaunee Counties Medical Society at a meeting in Green Bay, May 26, voted to endow a room in the old Fort Howard Hospital building, Green Bay, and dedicate it to the memory of Dr. William Beaumont, who had his office in the building when he was stationed at Fort Howard. The society plans to gather as many Beaumont relics as possible in the room and may eventually establish its library there.——Members of the Fond du Lac, Outagamie and Green Lake county medical societies were guests of the Winnebago County society, at Sunny View Sanatorium, Winnebago, May 20, when Dr. Joseph W. Gale, Madison, spoke on "Surgical Methods in the Treatment of Pulmonary Tuberculosis."——Drs. Louis Bothman and Francis L. Lederer, Chicago, addressed the Central Wisconsin Society of Ophthalmology and Oto-Laryngology, June 4, in Green Bay. Dr. Bothman spoke on "Cataract Surgery in India" and "Detachment of the Retina: Diagnosis and Treatment," and Dr. Lederer, "Mastoiditis: Its Pathology and Indications for Operation" and "Present Status of Malignancies About the Head and Neck and Their Management."——Drs. Austin C. Davis and John M. Berkman, Rochester, Minn., addressed the Chippewa County Medical Society, Chippewa Falls, May 10, on "Adenomatous Goiters" and "Chronic Fevers," respectively.——Drs. Frederic W. Schlutz, Chicago, and Harold B. Miner addressed the Milwaukee Pediatric Society, June 8, on "Significance of the Vitamins in the Nutrition of the Child" and "Congenital Heart Disease," respectively.

GENERAL

Hospital Meeting.—The hospital associations of Virginia and North and South Carolina held a joint meeting at Richmond in May. Paul H. Fesler, Chicago, president of the American Hospital Association, addressed the opening meeting on "Caring for the Veteran in Civilian Hospitals." Dr. Richard B. Davis, Greensboro, was elected president of the North Carolina society; John Bell Williams, D.D.S., Richmond, for Virginia, and Mr. F. O. Bates, Charleston, for South Carolina.

New Members of National Board of Examiners.—At the annual meeting of the National Board of Medical Examiners in Washington, May 2, Dr. Walter L. Bierring, Des Moines, was elected to the board to succeed John G. Bowman, LL.D., Pittsburgh, and Dr. Harold Rypins, New York, to succeed Dr. David Strickler, Denver.

Exhibit on Eugenics.—An exhibit showing the history, content, present researches and trends in eugenics is planned in connection with the Third International Congress of Eugenics, which is to be held at the American Museum of Natural History, New York, August 21-23. The exhibit will be on view at the Museum from August 22 till September 22. Materials for the exhibit will be shown in (1) pedigree charts, (2) statistical charts and tables, (3) photographs and maps, (4) models, casts and drawings, (5) books and scientific papers, (6) scientific apparatus, and (7) living specimens. The main subjects to be represented are: human traits and qualities, human genetics, heredity and environment, heredity and development, human migration, mate selection, differential fecundity, population studies and applied eugenics.

Births Decline in World Centers.—The birth rate in twenty-four of the world's largest cities showed a decline in 1931 of more than 5 per cent from the 1930 rate, according to figures recently made available for forty-two cities. Only two cities, Glasgow and Rio de Janeiro, recorded increases. Berlin had the lowest rate, 8.7 per thousand of population, while Dresden and Frankfort-on-Main were only slightly larger. The highest rate reported was for Madras, India, 40.5. In the United States Pittsburgh had the highest rate, 20.9, but all the fourteen American cities with populations of more than 500,000 reported that the birth rates had declined during 1931. The declines varied from 22 per cent in Boston to 1 per cent in Washington, D. C. The lowest rate in the United States was that of San Francisco, 11.8.

Foundation for Cancer Research.—William H. Donner, retired steel manufacturer of Villanova, Pa., has established a fund of $2,000,000 for the furtherance of cancer research on a world-wide basis, to be known as the International Cancer Research Foundation. Mr. Donner stipulated that the fund should not be used to erect new buildings or laboratories, but to assist scientists to develop new theories and new research workers and to increase general interest in the cancer problem. The income of the fund is to be distributed to institutions throughout the world, not more than 35 per cent to any one and not more than from 50 to 60 per cent within the United States. Mr. Donner, who established the fund because of the death of a son in 1929, will act as president; Thomas S. Gates, LL.D., president of the University of Pennsylvania, Philadelphia, is vice president, and the directors are Edward R. Weidlein of Mellon Institute for Industrial Research, Pittsburgh, and former Senator George Wharton Pepper, Philadelphia.

News of Epidemics.—Reports to the U. S. Public Health Service from forty-seven states for the four weeks ended May 21 showed 679 cases of typhoid. This is the lowest figure in four years for the corresponding period, only the South Atlantic and South Central states showing any increase. Newspapers recently reported an outbreak in a Negro settlement near Charleston, W. Va., in which a family of seven had the disease and three died. Prompt immunization of all inhabitants of the community checked the spread of the infection. Seven cases in a family near Arcadia, Ind., were traced to contamination of a well on the premises. Pollution of a brook near a baseball diamond was found responsible for two cases in high school players in Worcester, Mass. Thirty-one deaths have been reported from North Carolina for the first quarter of the year, more than twice as many as for the same period in 1931.——Measles has been epidemic in New York State for several weeks, the high point having been reached during the week ended May 21, when 2,643 cases were reported. The number had declined to 1,749 for the week ended June 11, according to *Health News*.——Drs. Fred L. Soper and Allen M. Walcott of the Rockefeller Foundation have gone to La Paz, Bolivia, to assist the Bolivian government in fighting an epidemic of yellow fever in the Santa Cruz district, it is reported. The Foundation has agreed to subscribe $18,000 and the government, 75,000 bolivianos to finance the campaign for eighteen months.

PHILIPPINE ISLANDS

Medical Activities.—A museum depicting the progress of medical and surgical science in the islands will be developed at the University of Santo Tomas, using as a nucleus the collections of Dr. Jose P. Bantug, Manila, who suggested the plan.——Members of the Philippine Health Service gave a banquet, March 28, in honor of Major George F. Lull, health adviser to the governor-general, who returned to the United States. A watch was presented to Major Lull.——Dr. Sixto A. Francisco, Las Banos, is a delegate to the Pacific Regional Health Conference to be held in Honolulu in July and will later make an investigation in the United States of the health of students as affected by college work and extracurricular activities, especially athletics.

CANADA

Physicians Urge Control of Alberta Radium.—Immediate action to prevent the deposits of radium recently found in northern Alberta from falling into the hands of a foreign monopoly was urged on the Canadian government in a resolution adopted by the council of the College of Physicians and Surgeons of Alberta at a recent meeting. The resolution pointed out that heretofore the supply of radium has been limited by the control of the supply by the European-African syndicate and cited reports that foreign commercial interests are now making efforts to obtain control of the Canadian pitchblende deposits.

Resigns as Dean at Eighty-Four.—Dr. John Stewart, 84, has resigned as dean of the Faculty of Medicine of Dalhousie University, Halifax, N. S. Born on Cape Breton Island, Dr. Stewart began his medical studies at Dalhousie but was graduated from the University of Edinburgh Faculty of Medicine in 1877, and for a year was house surgeon under Sir Joseph Lister in London. In the World War Dr. Stewart served overseas as commander of the No. 7 (Dalhousie) Stationary Hospital Unit and in March, 1918, was appointed consulting surgeon at headquarters. On his seventieth birthday King George V reviewed his unit in France. After his return he was appointed dean of the faculty of medicine at Dalhousie in 1920. He had been professor of surgery in the school for many years. The successor to Dr. Stewart is Dr. Harry Gondge Grant, a graduate of Dalhousie in 1912, who is at present connected with the state health department of Virginia, at Richmond, as a member of the International Health Division of the Rockefeller Foundation. Dr. Grant spent several years studying in England and was lecturer in medicine at his alma mater from 1921 to 1925. He also succeeds the late Dr. William H. Hattie as professor of public health.

PORTO RICO

Dr. Bachman Appointed Director.—George W. Bachman, Ph.D., associate professor of parasitology in the School of Tropical Medicine of the University of Porto Rico under the auspices of Columbia University, has been appointed director of the school. Dr. Bachman, who was appointed acting director at the beginning of the past academic year, succeeds Dr. Earl B. McKinley, who resigned to become dean of George Washington University School of Medicine, Washington, D. C. A native of Ohio, Dr. Bachman received the degree of doctor of philosophy from the University of Chicago in 1927. He was also promoted to a full professorship in parasitology.

FOREIGN

Memorial to Dr. Todd.—An annual prize in medical jurisprudence will be established at the University of Sydney, Sydney, Australia, in honor of the late Dr. Robert Henry Todd, as soon as sufficient funds are available. Dr. Todd was lecturer in medical jurisprudence at the university for twenty years. Subscriptions may be sent to the medical secretary, New South Wales Branch of the British Medical Association, British Medical Association House, 135 Macquarie Street, Sydney.

Medical Center in Mexico.—A complete new medical center in connection with the School of Medicine of Nuevo Leon, Monterrey, was recently arranged for when the governor and secretary of the state of Nuevo Leon signed the contracts. The plan now in formulation contemplates a new medical school, a general hospital of 500 beds, a nurses' home, a separate wing for tuberculosis, one for the insane, and another for communicable diseases. It is expected that the entire project will require about five years to complete. The governor has appointed a special committee of the Monterrey branch of the Mexican Medical Association, headed by Dr. Francisco L. Rocha, to act in an advisory capacity. At present there is in the city of Monterrey a hospital of about 350 beds known as the Gonzalez Hospital, constructed about 100 years ago. Here are concentrated units for the treatment of the insane, tuberculosis and communicable diseases, all of which are antiquated, it was said, and must be replaced by modern accommodations.

Chinese Physicians and Marriage.—To obtain information concerning the distribution of physicians in China the medical schools of Cheeloo, St. John's, Yale-in-China and Hacket sent questionnaires to 600 graduates, of whom 211 returned usable replies. Among other things, the questionnaire asked the age at time of marriage, and the number of children with their ages. According to the *Chinese Medical Journal*, 171, or 81 per cent, of the 211 graduates were married. In this group of Chinese physicians who gave the necessary dates, eighty were married before graduation and sixty-three afterward. In this total of 143, marriage occurred an average of 2.3 years before graduation. The age of marriage varied from 14 to 46 years, though in three instances the ages were given as 4, 9 and 12 years. The greatest number of marriages occurred between the twenty-fifth and twenty-ninth year, the peak age being 26; 14 per cent were married before the age of 20. These results are in marked contrast with the age of marriage in the general population, the journal states. Among 4,000 men attending an outpatient medical clinic in Peiping, 54 per cent gave their age at marriage as less than 20. The Chinese married physicians in the questionnaire group averaged 3.46 living births per family, or one birth for 3.26 years of marriage.

Congress on History of Medicine.—The ninth Congress of the International Society for the History of Medicine will be held in Bucarest, Rumania, in September. Subjects chosen for discussion are the evolution of medicine in the Balkan states and the protection of Europe against bubonic plague. Those who wish to read papers are requested to send the title and a summary of their papers as soon as possible to the office of the congress, Bucarest II, Str. Stirbey Voda, 86. Lectures are limited to forty-five minutes and explanations to fifteen minutes and may be in English, French, German, Italian or Spanish. Participants may wish to join others at a general meeting place, which is being arranged in Trieste. Stopovers will be arranged at Athens, at Istambul and at Constantza, Rumania, where the party will take the train for Bucarest.

LONDON

(From Our Regular Correspondent)

June 4, 1932.

Lord Moynihan on the Advance of Medicine

In his Romanes lecture at Oxford, Lord Moynihan, president of the Royal College of Surgeons, said that surgery had almost reached the end of its progress along the lines which it so far had followed. The most extensive and delicate operations were carried out on every organ in the body, including those only recently made accessible, with a success that not even Lister himself could have believed possible. New methods of treatment might no doubt appear in their further development, but so long as cutting operations of the kind now practiced had to be applied, it was hardly possible that their success could be improved on except through increasing the patient's powers of resistance by preliminary preparation. Heretofore surgeons had been engaged in discovering methods of dealing with structural diseases by mechanical devices. Now they must concern themselves with recognition and correlation of those manifold bodily ailments which result from changes in the function of organs. Patients sought their aid only, as a rule, when something had gone seriously wrong. Hospitals were filled with examples of advanced disease. What would surely advance their knowledge and perhaps lead on a large scale to prevention of disease was hospital research on those suffering from slighter ailments. At present, research work and clinical inquiry were conducted at far distances from each other by men who rarely met. Experimental work should more often be suggested, and even carried out, by those whose experience in clinical work has shown them exactly where investigation might become most profitable. Physiology today was unhappily losing the close relation it had formerly had with clinical medicine. The cleavage was all to the advantage of physiology, all to the detriment of clinical medicine. Physiology had wandered away on its own researches. Its biologic inquiries had been conducted almost exclusively on animals, though during this time the surgeon had gained incalculable victories for clinical medicine. In the future the physiologist and the surgeon should make a common attack on the innumerable mysteries of disease. The greatest of all discoveries in medicine throughout the ages had been made by those directly concerned with clinical problems.

The Medical Problems of Contraception

A conference on the medical problems of contraception has been held under the auspices of the National Birth Control Association. It was attended by more than 200 laboratory workers, medical officers of clinics, health officers and private physicians. Sir Thomas Horder is president of the National Birth Control Association.

Dr. L. F. Hogben, professor of social biology at the London School of Economics, discussed biologic methods of contraception, which were of two kinds—one based on serologic technic, the second on the control of reproductive activity by hormones circulating in the blood stream. The injection of seminal fluid into warm-blooded animals resulted in the formation of spermatotoxins, which in the female produced sterility through their presence in the secretions of the genital tract or, perhaps, in the germ cells themselves. But much research remained to be done on the duration of the spermatotoxic effect before it would be possible to apply the serologic method with success. As to the second method, it was possible to destroy the reproductive elements of the gonads without affecting the cells that manufactured the hormones on which sexual behavior depended. He suggested that the two ovarian hormones estrin and lutein might be used for the production of sterilization.

A long discussion took place on the methods of birth control in use. Of mechanical contrivances, the vaginal diaphragm pessary was stated to be popular.

Road Accidents in 1931

A return just published shows that during 1931, in Great Britain, 6,691 persons were killed on the roads and 202,119 injured. In 1930 the figures were 7,305 killed and 177,895 injured. Thus while the reduction of fatal accidents is a matter for satisfaction, it is offset by an increase in the total number of accidents. Vehicles to which fatal accidents were attributable were as follows: private automobiles, 1,813; automobile vans and trucks, 1,399; motorcycles without pillion passenger, 980; motorcycles with pillion passenger, 451; automobile omnibuses and coaches, 736; motorcycles with sidecar, 184; electric cars and trolly omnibuses, 118; automobile cabs, 65; pedalcycles, 632; horse-drawn vehicles, 103; horses ridden and led, 18.

A Consultant Service Under the National Health Insurance Act

The national health insurance act provides only a service of general practitioners. If the services of a consultant or specialist are required the patient must either pay for it or go to a hospital. At a conference of the faculty of insurance, Dr. G. C. Anderson, deputy medical secretary of the British Medical Association, delivered an important address on the value of the provision of a consultant service. He pointed out that it was not long since the family doctor or general practitioner did not need to worry about roentgen examinations and the intricate laboratory methods of diagnosis and treatment that have been evolved of recent years. These aids are used in private practice, and he thought that insurance practice should approximate it as far as possible. The insurance physician has to depend on the outpatient department of hospitals for special diagnostic services, and as now organized they afford him little help in keeping abreast of modern medicine. The best way to sharpen his faculties and bring his methods down to date would be to bring him into active association with a hospital in his own area. The crying need of the general practitioner is for greater access to such an institution where he will find opportunities for acquiring knowledge at present difficult for him to obtain. Little such cooperation exists now, as the insurance practitioner rarely sees the consultant whose advice he is anxious to obtain, because of the impracticability of such an arrangement in the present overcrowded state of the outpatient departments. The provision of diagnostic facilities in the early stages of diseases, the early access of the insurance practitioner to the specialist in difficult and obscure ailments, and the consequent early treatment would prevent acute ailments from becoming chronic and should before long reduce the amount that is being expended on sick benefits.

The Religion of a Physiologist

Prof. J. S. Haldane stands alone among physiologists in troubling about philosophical problems and insisting that the phenomena of life transcend physical explanation. His Scottish blood may be responsible for this. Though not a member of any church, he delivered an address for "The Christian Evidence Society," entitled "Reality as Spiritual." He said that if the universe surrounding us is no more than the universe described by the physical sciences, we could proceed to prove from observation and experiment that we were also no more than part of it. But this conclusion was completely unwarranted. Our universe was the universe of our experience, while the universe of physical science was only an idealized universe, stripped of all the values actually present in it, since the conceptions of physical science, however useful for practical purposes, were incapable of describing values. The actual universe of our experience was a universe of personality. In it we found the fact of moral obligation—to promote and cherish truth, right and beauty so far as we could recognize them. That obligation was common to all men and its recognition united us and at the same time showed us that our experiences were no mere separable things but that within us was revealed the all-embracing personality which men called God. That fact gave to truth, right and beauty their authority, and so gave objectivity to our universe of experience as the manifestation of God.

Spahlinger's Reticence

In THE JOURNAL, March 5, page 828, it was reported that after years of secrecy, for which he has always been severely criticized in this country, Spahlinger professed to disclose his secrets by stating how his vaccines are prepared. But Sir Thomas Horder (THE JOURNAL, April 23, p. 1487) pointed out that he had failed to disclose how his serum was prepared, although it was with this that for twenty years he has claimed to cure tuberculosis. A further criticism of his reticence has come from Sir Frederick Menzies, health officer of the London County Council. He says that although Spahlinger claims that he has disclosed full details of his method of preparing his vaccine, the fact remains that so much information of fundamental importance is missing that no two competent bacteriologists, working independently on his formula, would be likely to produce the same preparation. He made inquiry into the Spahlinger method at the request of the Central Public Health Committee of the London County Council. His report is as follows: "From the information available there is no evidence which would at present justify the trial of this vaccine, under the auspices of the council, on human beings."

Is Multiple Sclerosis of Syphilitic Origin?

French pathologists are divided on the question of the etiology of multiple sclerosis. Some regard the disease as an infection due to a filtrable virus, although no case of contagion has ever been reported, and endeavor to find a curative serum obtained from monkeys inoculated with the pathologic nerve substance. Others regard it as a late manifestation of hereditary syphilis. At a recent meeting of the Société des médecins des hôpitaux de Paris, Mr. Mendelssohn presented a patient who showed unmistakable signs of hereditary syphilis. She presented a typical case of multiple sclerosis but was so much improved by syphilitic treatment that she may be said to have been cured. Paraplegia, tremor, abolition of the abdominal reflex and of the reflexes of the velum palatinum, exaggeration of the patellar and achilles reflexes, and the condition of the cerebrospinal fluid, all cleared up after four series of treatments with compounds of arsenic, bismuth, mercury and the iodides. This treatment was first instituted because the patient was affected with a mitral stenosis and because her father was syphilitic and her mother presented a positive Wassermann test. Mr. Mendelssohn emphasized the importance of the fact that the cerebrospinal fluid had returned to normal, which is exceptional in the observations of improvements heretofore published. Mr. H. Dufour supported the opinion of Mr. Mendelssohn as to the syphilitic etiology of multiple sclerosis and presented a patient whom he had been treating for twelve years with an antisyphilitic treatment repeated every year. The symptoms, which were progressing when treatment was first begun, have been stabilized for twelve years, which appears to indicate a favorable action of the drugs employed. The author stated that he had accepted since 1916 the syphilitic origin of multiple sclerosis, regarding it as an attenuated hereditary syphilis, but he added that he would be the first to grant the disease its autonomy if it should be shown to be due to a specific infectious agent. All the arguments previously brought forward against the syphilitic origin of tabes and dementia paralytica are the same, he said, as are now urged against the syphilitic origin of multiple sclerosis. Rational, carefully supervised syphilitic treatment has never aggravated multiple sclerosis but has often brought improvement.

Irradiation Over the Suprarenal Capsules in Endarteritis Obliterans

Mr. Zimmern has brought into favor in France the application of roentgen rays to the suprarenal capsules to check the physiologic mechanism of endarteritis obliterans. In collaboration with Chavany and Brunet, he has reported several cases of extensive dry gangrene in which a cure was effected or which were arrested in their evolution by radiotherapy applied to the area of the suprarenal glands. Mr. Leroy des Barres presented recently to the Academy of Medicine a case of endarteritis obliterans of the right external iliac artery, with gangrene of the leg, in which high voltage roentgen therapy applied to the suprarenal capsules brought about such a notable improvement that the amputation of the thigh could be performed at a much lower level than the appearance of the leg at first appeared to justify. Radiotherapy caused an arrest of the gangrene and then an improvement in the circulation, so that the author regretted that he had not resorted to this method earlier, believing that if he had done so the amputation could have been made at a still lower level. Mr. Zimmern himself held that suprarenal irradiation should always be carried out in endarteritis obliterans whenever there appears a menace of gangrene. In an analogous problem, that of true arterial hypertension of suprarenal origin, Mr. Santucci recommended, in an article published in the *Clinique*, the division of the left splanchnic nerve in accordance with the Pende method. This nerve, as he showed in 1903, controls the secretory functions of the suprarenals, and the splanchnic plexuses as a whole exert a vasoconstrictive action on all the vascular area of the abdomen. The division of the splanchnic nerve causes a frank and durable lowering of the arterial pressure in persons with hypertension, whereas all hypertension remedies bring about only a temporary lowering. Durante resected the greater and the lesser left splanchnic nerves in a case of juvenile gangrene due to endarteritis obliterans and in a case of generalized Raynaud's disease, both of which were associated with arterial hypertension, and obtained excellent results. After the intervention, the hypertension retrogressed steadily. Mr. Zimmern holds that high voltage roentgen therapy of the suprarenals will secure just as good results without surgical intervention.

Facial Expressions in the Blind

Mr. Dumas, professor in the Collège de France, who has specialized, as has Pierre Janet, in philosophical questions considered from the psychiatric point of view, has been carrying on research for years on the "laws" of mimicry, having extended his investigations further than Darwin. He recently presented to the Academy of Medicine the results of his research on the expression of feelings, by the mimicry of the face, in the blind. The human face, by means of spontaneous muscular phenomena, gives expression to the feelings within: the joy, sadness, fear, and the like. Inversely, persons likewise sometimes endeavor to delude an observer into believing that certain feelings are being experienced by reproducing voluntarily corresponding muscular contractions, which then take on the value of a mute language. Professor Dumas raised the question as to the origin of this mimicry; that is to say, whether it originates in the form of a remembrance of musculocutaneous sensations that have been experienced or whether it originates as a visual memory and copy of the attitudes and expressions seen in others. To determine this point, he conceived the idea of studying persons who have been blind from birth. Thirty-three observations proved to him that persons blind from birth are unable to express by mimicry feigned emotions. They had spontaneous expression, like anybody else, but they are unable to imitate such expressions; that is to say, to reproduce them without the cause that creates them. In this domain, as in many others, the blind appear able to make up for the loss of visual gifts by their accentuated tactile sense. Some of the persons studied, by applying the back of the hand to their face, produced movements corresponding to spontaneous expressions and, after some preliminary experimentation, succeeded in reproducing some elementary mimicry. It would be rendering an important service to the blind to teach them to develop forms of mimicry.

A Surgical Sound Film

Professor Gosset recently presented before the Academy of Medicine a sound film, prepared under his direction, by Mr. J. Benoit-Lévy, which opens a new path for the educational film. This film is designed to show the various stages of a surgical operation (an appendicectomy), and Mr. Gosset, for greater clarity, used the motion picture. In the first part of the film, a succession of pictures show the various stages of the operation, while one hears the voice of the professor describing them in a clear and precise manner. In the second part is presented the real operation, the various stages of which are exactly superimposable on the motion pictures previously projected. Mr. Gosset, after his presentation, explained that it had been his desire to produce a film suitable for instruction, pointing out the great interest that surgical science has in recording its various forms of technic in a permanent manner. He looked over recently, through the courtesy of the son of Dr. Doyen, the films that were taken long ago of diverse operations performed by the latter, which enabled Gosset to take account, after many years, of what was good and bad. One can judge thus of the improvement in the technic and of the progress that science has made. Such films have therefore considerable interest for preservation in the archives of the history of surgery. The audience had one criticism to offer on Mr. Gosset's film. The presentation was a little too rapid to permit them to follow all the details of the operation.

The Significance of Tuberculous Bacillemia

The presence of tubercle bacilli in the blood constitutes today a peculiar problem. A direct examination of the blood is usually negative. But the cultivation on various mediums is sometimes positive, and a positive inoculation into guinea-pigs serves as almost certain proof of the presence of the bacillus. Nevertheless, Mr. Izard and Mr. Thiry of Toulouse, by hemoculture in a Loewenstein medium or in a Petrov medium, were able to discover the bacillus only in 13.02 per cent of the observations made on twenty-three patients and fifty-one guinea-pigs, all affected with frank tuberculous lesions. The search in persons with articular rheumatism and erythema nodosum was negative, although the authors expected positive results. They concluded from these observations that bacillemia, contrary to the opinion of Loewenstein, is only a rather rare sign of tuberculosis and of little significance. Even in the forms of acute tuberculosis only a simple migration of bacilli is involved and not a massive septicemia. However, the conception of atypical tuberculosis, by supplying evidence for the filtrable form of the tuberculous virus, may possibly increase the percentage of positive cases. At the same time, J. Troisier and T. de Sanctis Monaldi carried on similar researches and reached peculiar conclusions. By using the Loewenstein medium and the Petragnani medium with asparagin but without peptone, they were more fortunate in their researches. They did not study tuberculous persons but patients affected with manifestly nontuberculous disorders: an ordinary curable pneumonia, a fatal case of streptococcia (type Osler), and suppurative cerebrospinal meningitis with meningococcus type A. They secured every time, by hemoculture, typical human bacilli, frankly virulent for the guinea-pig. Active tuberculosis, however, did not develop in one of these patients. The pneumonia patient subjected four months later to a radiologic examination was found to be cured. The patient with Osler's disease did not present at necropsy any evidence of tuberculosis. The patient with meningitis died following a new augmentation of the meningococcus type A, in spite of the specific serotherapy. In endeavoring to interpret this tuberculous bacteremia associated with a nontuberculous acute disease, the authors held that, in their patients, the acute coccal infection had brought about the appearance of the tuberculous virus that had existed until then in an almost saprophytic state in the organs. The tubercle bacillus found under these conditions in the blood cannot be considered the pathogenic agent of the acute disease but must be regarded as a virus without present pathogenic effect. To sum up, bacillemia is usually absent in frankly tuberculous patients, whereas it may be encountered in nontuberculous acute diseases without having any particular significance.

Prospects of Medical Students in Germany

The Verband Deutscher Medizinerschaften has published notes on overcrowding in the medical profession. The following facts are emphasized: The course in medicine from the beginning of study up to the time of obtaining a license to practice comprises seven years; eleven semesters of study, one semester for examinations, and one year internship, cost the student about 10,000 marks, or $2,380, and the state contributes a like sum. Unless a physician is admitted to panel practice, a modest income is at present almost impossible in Germany. There are restrictions governing admission to panel practice; for instance, there may not be more than one physician to 600 insured persons. This proportion has already been reached; hence new admissions are made only to fill vacancies. A preliminary period of three years during which new entrants must serve as assistant physicians, which is a welcome innovation in itself, has been agreed on between the leagues of the medical organizations and the *krankenkassen*, or sick benefit associations. The number of existing assistantships is, however, inadequate for the carrying out of the agreement thus entered into. A portion of the applicants must therefore accept positions as unpaid volunteers or wait for an opening. The fees for the treatment of the insured members of sick benefit associations are exceedingly low. In addition to the medical care proper, there is considerable clerical work required by the *krankenkassen*, for which no additional compensation is granted. It is, however, almost impossible for a young physician to build up an adequate private practice that will relieve him of the necessity of accepting panel service. There are few communal, provincial and federal positions, and vacancies are rare. According to the statements of eminent investigators, the medical profession can absorb no more than from 1,100 to 1,200 oncoming physicians each year without disrupting the profession by the unduly accentuated struggle for existence. That would entail the destruction of a profession occupying a high ethical position. The new medical students enrolled for the past few years have greatly exceeded the estimated number of assimilable young physicians: 1928-1929, 3,350; 1929-1930, 3,795; 1930-1931, 4,267. It is evident that, during the past three years, 7,800 more medical students than needed have received training. The number of medical students, however, continues to increase, whereby the number of physicians without adequate income is increased by further thousands. Hence the German people is facing the growing menace of an inevitable demoralization of an overcrowded medical profession, which fact calls for prompt intervention. Action must be taken to induce those students who study medicine only for the lack of something else to do and those who in their mental and personal qualities do not rise above the average, if they even equal it, to give up their medical studies. Only the best will be capable of enduring the economic distress without departing from the ideals of the medical profession. This standpoint of the societies of the medical students, as representative of the whole body of medical students and the new medical graduates, will be readily understood; but will anything be done to bring relief? The authorities have sought in vain for a way out of the dilemma, which at the present time appears almost unsolvable. It is to be hoped that the new regulations with respect to examinations, which are being considered and are expected to be completed soon, will open up the way (or, in one sense, will block the way). Without governmental aid and controlling regulations, nothing will be accomplished; for what student is willing to admit that he is not competent, and what student is wise enough and sufficiently self-critical to recognize that he is below the average in intelligence. It is a sad thing for those of the older generation to contemplate the youth of the present day and to note the painful sacrifices that the freedom of learning must make in endeavoring to adjust itself to the times.

Municipal Radium Commissioner Appointed

In the interest of the municipal insurance system of Berlin, the mayor has appointed the chief physician of the Werner-Siemens Institute for Roentgen Research of the Städtisches Krankenhaus Moabit as a special commissioner to supervise roentgen installations, and radium and film depositories, and the electromedical installations in the municipal institutions. The mayor has requested all the municipal plants affected by the order to assist the commissioner in every way possible in his inspection and to comply with his instructions. The city hopes in this way to be able to protect itself against damage claims. Furthermore, this competent centralized supervision affords increased protection to the personnel of the installations in question.

Antisepsis in Barber Shops

Campaigns have been waged of late against insanitary conditions in barber shops, and demands have been made that police regulations be issued to control them. Now Medizinalrat Dr. Schrader has expressed his views. He points out that there is only one regulation that would eliminate all danger; namely, a regulation requiring every customer to supply his own razor, towel, brush, soap, comb, brush, shears and the like. But that is not feasible; nor are such regulations possible as would require barbers to use fresh linen for every customer, and the cleansing of all utensils after being used on a customer; for that would make the prices prohibitive. It is more important to make the barber familiar with the necessary hygienic measures and to call the attention of the public, at the same time, to existing evils. If the customer complains of insanitary practices and threatens to withdraw his patronage, the barber will usually take more care. Schrader mentions several unhygienic practices that he has found common among barbers. Some apply the back of their left thumb to their lips and draw the razor blade over the moistened surface to test the keenness of its edge. In that manner infectious diseases may be transmitted to patrons. Another practice of barbers is to use a piece of newspaper to wipe off the soap on a razor blade. In this way infectious material may be carried to a patron. Barbers' apprentices should have their attention called to the contraindications to the following procedure: In going over a customer's face the second time, barbers will often shave close after moistening the skin with clear water only. This practice gives rise to minute skin injuries, creating ports of entry for infectious organisms. Instruction in regard to these and similar unhygienic practices will accomplish more than police regulations and the imposition of fines.

ITALY

April 31, 1932.

Discussion on Traffic Accidents

The Società italiana di medicina sociale held recently its second national congress in Rome, under the chairmanship of Prof. Carlo Foà, director of the Istituto di fisiologia of the University of Milan. Professor Gemelli of Milan discussed the practical value of psychotechnics for the alleviation of the consequences of traffic accidents.

Professor Ciampolini, sanitary inspector of the railways, presented a paper, in collaboration with Professor Boveri, on the morbid factors in drivers of automotive vehicles that predispose to traffic accidents (emotion, excitement, irresoluteness, timidity, and the like). He considered the importance of the medical certificate as the basis of granting drivers' licenses and emphasized the need of observing candidates for licenses in all their neuropsychic manifestations, with particular reference to defects of vision and hearing.

Professor De Bernardinis, of the Ufficio centrale di statistica, gave statistics on street accidents for the period 1926-1930, which showed that the number of accidents had doubled.

Professor Cazzaniga spoke on the part played by the pedestrian in causing street accidents. Various errors are attributed to pedestrians, whereas the true cause of the accidents is usually a misunderstanding on the part of the pedestrian and the driver of each other's mutual intentions. The speed of the vehicle is not the determining factor but the condition of irremediableness in the situation. The safest pedestrian is the one who moves slowly, even though threatened in a traffic jam.

Professor Ponzo, of the University of Rome, presented a paper on the psychophysical factors that predispose to traffic accidents. The physician must endeavor to exclude all persons who are ill adapted to driving, and particularly those who, on the basis of psychotechnical research, present such defects as to justify their elimination. The examination should not be on an exclusively psychotechnical basis but should be preceded by a fundamental clinical examination of the applicant to establish the absence of pathologic factors that predispose to street accidents.

Professor Palmieri of Naples spoke on the part played by alcoholism in the causation of traffic accidents.

The Crusade Against Tuberculosis

The meeting of the Federazione per la lotta contro la tubercolosi was held at Palermo under the chairmanship of Professor Manfredi of the University of Palermo. Cannavò reported on a study of forty patients affected with pulmonary tuberculosis, for the purpose of studying the behavior of the acid-base equilibrium. In every case the degree of changes in the acid-base equilibrium is proportional to the condition of the pulmonary ventilation and to the compensation, if any, on the part of the other organs, of the deficit ascribable to the lungs.

Lucacer spoke on the prognostic value of the functional test of the reticulo-endothelial system in pulmonary tuberculosis. He recalled the proposal of Wedekind and Loewenstein to use the variable retention index of congo red in the various anatomoclinical forms of pulmonary tuberculosis, for their exact differentiation. He applied this test to some hundred tuberculous patients with results that agree with those secured by the proponents of the test. He found, namely, that the exudative types present a bad retention index (5.90 per cent of congo red is found in the blood plasma an hour after the injection), probably in relation with a certain degree of insufficiency due to an overloading of the reticulo-endothelial system, because of the reaction to the infection. He raised the question as to whether the congo red test could furnish also prognostic factors, and with that in view he continued the research. The results confirmed the correctness of his assumption. In forty infected patients, he found that with an improvement in the local and general conditions of the patient the retention index improved and approached normal values, while it became worse if the patient gave evidence of exacerbation.

Piazza spoke on a test described by him in 1923 that consisted in applying to the urine of tuberculous patients an antiserum secured by injecting old tuberculin (Koch) into a normal rabbit. The test presented two phases, one precipitant and the other lytic. The first is immediate; the second, delayed but constant, is applied by means of the biuret test. The speaker affirmed that his test is specific for pulmonary tuberculosis in febrile periods and recommended some refinements in the technic. He cited control researches that had been made by other authors; among others, those of Santoli, Bellavia, Lucacer and Franco.

Association of Stomatologists and Dentists

The general assembly of the Federazione stomatoiatrica italiana was held recently at the Policlinico di Roma, under the chairmanship of Professor Perna. The constitution of the association of the stomatologists and dentists of Italy was discussed and approved. The constitution will contain this article: "The ranks of the dentists accept without reserve or restrictions the stomatologic idea."

Malaria in the Province of Milan

Professor Piccinini, "provincial physician" of Milan, reported recently to the Comitato antimalarico (malaria commission) the present conditions in the province from the standpoint of malaria infection. The disease is at present confined to a few districts but nevertheless deserves serious consideration. During the past year, twenty-four dispensaries were established for the summer season; chemical treatment of the stagnant waters was carried out, and the topographic malaria chart of the province of Milan was completed. By statistical reports and experimental researches the importance of zootechnical development in the crusade against malaria was confirmed. A study on the relations between rice fields and anophelism was completed and revealed that well cultivated rice fields are not the cause of anophelism.

Trachoma in the Colonial Schools

In combating trachoma, which is still widespread among the native population of Tripolitania, the government operates chiefly through the colonial schools. In Tripoli there has been, since 1916, a special school for trachomatous children. The school has been recently enlarged and better equipped, in order to give to a greater number of children the preventive and curative benefits of medical treatment. At present, the enrolment comprises 597 pupils, which are divided into thirteen classes. A recent report of Professor Festa shows the results secured by this institution, which in a single year brought about the recovery of 178 children.

A Case of Alkaptonuria and Ochronosis

Prof. G. Castronuovo reported recently, to the Accademia delle scienze medico-chirurgiche in Naples, a case that he observed in which marked alkaptonuria and mild ochronosis occurred in the same patient. The cases of alkaptonuria heretofore described in the literature total not more than a hundred, and the cases of ochronosis are still more rare (less than forty). It is rare to find the two conditions in the same patient, although seventeen such cases have been reported in the literature. The patient observed by the speaker was 52 years old and had been alkaptonuric since her birth. From childhood it had been observed that her urine, although containing no sugar or blood, and which was of a clear straw color when voided, on being exposed to the air for some time turned gradually black, as if ink or coal had been mixed with it. The presence of alkaptone was confirmed by chemical tests. The speaker applied some of the urine to pieces of cartilage from a human cadaver and secured a characteristic blackening. Alkaptone, or homogentisic acid, which is derived from aromatic amino-acids, is eliminated unchanged in these patients, whereas in normal persons it is entirely burned up. In these patients, the protein metabolism is disturbed, especially in its disintegrative action, which lies at the basis of the clinical manifestations, among which attention may be called to the changes in the color of excrementa and the slow blackening of such tissues as the sclera, the cartilages, the ligaments and certain skin areas.

Meeting of the Medicosurgical Society of Pavia

The meeting of the Società medico-chirurgica of Pavia was held recently under the chairmanship of Prof. A. Ferrata. Introzzi spoke on puncture of the spleen in malignant granuloma, emphasizing its diagnostic value in the differential diagnosis of the splenomegalic varieties of malignant granuloma without involvement of the peripheral granular system encountered at necropsies. He described then the histologic picture and the appearance, in granulomatous splenomegalia, of the splenic juice obtained by means of the puncture in vivo, and brought out that the presence in it of giant mononuclear and polynuclear elements with numerous nucleoles, identifiable with the Sternberg giant cells, and the presence of elements of a histoid nature, identifiable with epithelioid cells, constituted a diagnostic factor of prime importance—superior to eosinophilia.

Callerio reported the results of his studies on lysozyme, a bacteriolytic substance first described by Fleming in 1922. He confirmed the activity and the diffusion of the lysozyme in nature, and suggested a refinement in the technic for the determination of the phenomena, which refinement consisted in testing the various substances in an emulsion of Micrococcus lysodeikticus in nutritive agar solidified in the form of thin flakes. On cultivating a number of species of bacteria in this medium, the speaker found that all developed as well as on ordinary agar, and that some strains belonging to the group of the enterococcus provoked evident phenomena of lysis similar to those produced by egg albumin and by other substances containing the lysozyme, which are manifested with the appearance of an illuminating halo around the colonies.

Rusconi studied the changes produced in the ovaries of white mice weighing from 5 to 6 Gm., following injection of the urine of a gravida, according to the method of Aschheim-Zondek. The speaker concluded that it is not a question of an early artificial maturation of the ovum but rather of a disturbance that manifests itself by endofollicular hemorrhages and changes in the miosis of the oocyte.

Bianchi spoke on Loewenstein's method for the cultivation of the tubercle bacillus in the blood. A series of control researches on the presence of the tubercle bacillus in the blood gave a negative result. Using data that he collected from the Loewenstein laboratory, the speaker explained the method followed by Loewenstein.

Death of Professor Soli

The death of Professor Soli, occupant of the chair of anatomy at the University of Palermo, is announced. Born at Milan in 1880, he was given charge, in 1922, of the instruction in pathologic anatomy at Sassari. In 1925, as a result of a competitive examination, he was assigned a chair at Bari, from which he removed to Palermo. In his studies on the thymus, he showed its importance in calcium and phosphorus exchange and established the relations of the thymus to other endocrine organs, particularly the genitalia. Other researches concerned the permeability of the placenta, the pathogenesis of tuberculosis, and the diapedesis of leukocytes through the walls of the stomach.

VIENNA

(From Our Regular Correspondent)

April 13, 1932.

The Assassination of Prof. Gustav Alexander

The profession and the public suffered a shock on hearing of the murder of the eminent otologist Prof. Gustav Alexander. An insane tailor, who, twenty-seven years ago, was operated on for a saddle nose by Alexander, then an assistant to Pollitzer in the ear clinic, had cherished feelings of vengeance toward the operator. Back in 1910 he made an attempt to kill Professor Alexander, but the attack failed and the assailant was placed in a psychopathic hospital, where he remained for twelve years. After dismissal from the hospital, he was taken home. There his paranoia developed into a delusion of persecution, under the influence of which he blamed Professor Alexander for all his misfortunes. A few days ago he returned to Vienna, lay in wait for the scientist, and killed him with five shots of his revolver as Alexander left his house.

The fame of the deceased physician was based chiefly on the fact that he introduced surgery into otology and published the results of work on the physiology and pathology of the auditory organs, which made him the leading authority in this field. His publications bear the stamp of a great scientist pointing out ways for the acquisition of new knowledge. His research gave otologists the strongest impulses toward further work. Born in 1873, he obtained his doctor's degree in 1898 and soon became assistant to Zuckerkandl in the anatomic institute, during which period he reported his striking research on the anatomy of the inner ear. He soon became first assistant in the Pollitzer clinic, and in 1907 he took over the ear department of the Policlinic as successor of Professor Urbantschitsch, which post he held until his death. He founded here an "Alexander school," which attracted physicians and students from all parts of the world. Alexander was held in high esteem by numerous physicians in America. As a specialist, he developed remarkable activity. More than 300 publications followed one another in close succession, each one a work of quality. For his researches on "The Auditory Organs of the Echidna" he received the Leuval prize, in 1904, from the otologic congress held in Bordeaux. He published articles also on "Deafness in Cretins," "The Auditory Organs of the Dancing Mouse," "Congenital Deafness," and "Lymphomatous Ear Diseases," and on the functions of the vestibule. His works on "Surgical Ear Diseases" and "Ear Diseases of Childhood," and his "Handbook of the Neurology of the Ear," published in collaboration with Marburg and Brunner, are standard authorities indispensable for the specialist and have been translated into many languages. His research on the problems of heredity, and on the perception of position in space, were interrupted by his death. In the operative technic of otology many important innovations and many cosmetic methods (ear correction) trace their origin to Alexander; the recognition of syphilitic disorders of the inner ear, operation on thrombosis of the sinus by exclusion of the jugular vein, and abscesses of the cerebellum, are inseparably connected with his name. His "Amerikaner Curs" and his operative courses were the most widely known courses in Vienna, being attended by large numbers of foreign physicians.

Death of Professor Lazar

Prof. Dr. Erwin Lazar, expounder of therapeutic pedagogy, died here recently, after a short illness, at the age of 55. The Vienna medical faculty has lost a remarkable personality. As assistant in the Vienna children's clinic, he developed the idea that backward children and juveniles who are menaced psychically by the influences of their environment require special education, in order, through correct pedagogic guidance, to become useful members of society. He devoted himself accordingly to the problem of children who are hard to train and educate, and he developed in this field masterful ideas. At the children's clinic, of which Pirquet later became the director, Lazar established and directed the department of therapeutic pedagogy, where mentally abnormal children were treated. He demonstrated that children sometimes develop criminal tendencies owing to errors in their training and education. In numerous articles, Professor Lazar discussed the treatment of mental disorders of children, and therapeutic pedagogy, and at many congresses he presented papers. His therapeutic pedagogy has been recognized as a model method of instruction. With his system it is possible, after a short period of observation, to find the correct treatment for every abnormal child, whether institutional or family care is required. In his department, a large number of foreign teachers and physicians learned the fundamental bases of the modern education of psychopathic children and are now applying his principles throughout the world.

The Profession and General Economics

At a recent session of the Gesellschaft für Volksgesundheit in Oesterreich, Professor Dr. Tandler discussed the connections between the medical profession and recent developments in economics. The fate of the physicians depends, to a great extent, on economic conditions. Physicians are so to speak contractors on a small scale. The family physician—in Europe, at least—has disappeared because mass consumption and mass production have disturbed the individual relations between the physician and the family. The physician is menaced by the same dangers as the small contractor: unemployment and lack of orders or contracts. The "individual therapy" expected of the general practitioner forces him to unload his responsibility on to the specialist, where the patient's funds are sometimes squandered. But if the practitioner takes the correct attitude, he can help his clients to economize; for he is the real administrator of the organic capital of the patient, a sort of demographic executive to whom is entrusted, to a large extent, the welfare of mankind. Professor Tandler approves the idea of placing the physicians on the same footing as the judges; for the continued existence of the physicians will not be assured until human society comes to recognize that its highest possessions—civil rights and good health—are administrative concerns of the community. He regards the present status of the physician as only a transitional stage. The future of medicine, in Professor Tandler's opinion, lies in the development of health insurance.

The Organized Crusade Against Cancer in Vienna

In the annual report for 1931 of the Public Health Service of Vienna, attention is called to the increase in cancer mortality in recent years. In 1920 the number of deaths in Vienna from malignant neoplasm was 2,400; in 1926 the number increased to 3,700 and in 1931 to 4,900. The number of deaths has therefore doubled in ten years. The cause does not lie in a progressive dissemination of the disease but rather in an improvement in the diagnosis and the greater average age of the population. The most important measure against this menace is a well organized crusade against cancer. For that purpose the municipality of Vienna has purchased 5 Gm. of radium and has established an institute for radiotherapy. In this institute, in addition to the well founded surgical treatment of cancer, the method of irradiation carefully tested in Stockholm and Paris is to be employed. All other therapeutic researches will be fostered. The systematic combating of cancer will be carried out in a manner to show the public that cancer, when diagnosed early, has a high degree of curability. When the terrible implication "incurable" has been divorced from the diagnosis of cancer, physicians will no longer hesitate to inform their patients that they have cancer. About thirty or forty years ago, the diagnosis "tuberculosis" spread much the same terror as does "cancer" today; and now, through indefatigable, organized control, it is recognized as curable. With this in view, Vienna has established consultation centers, where persons who are anxious or are actually ill can receive answers to questions from competent specialists. In positive cases, these patients are sent at once to the institute for combating cancer, where a detailed examination discloses the nature of the disease. A record card is made out for every cancer patient (even though he is being treated in some other institute), and his case is carefully followed up.

Politics in the Medical Schools

Ever since 1918, medical students of Argentina have been enthusiastic about reforms in medical education. The reformers do not approve of the new regulations in the schools. Whenever any of the supporters of the so-called universitary reform are questioned as to its purpose, the answer differs in each case. Theoretically the following are the principal aims: (1) to give the student body certain rights in the management of the schools; (2) to develop scientific research and to intensify practical teaching; (3) to give the students a broader understanding of life in preference to professional knowledge; (4) to help free the oppressed and to carry on the social redemption of humanity; (5) to give the opportunity to teach to all of those properly fitted, and (6) to provide for professorships of six years without right of succeeding to the same position. In the schools of Rosario the students do not recognize presidents, although they have head commissioners and secretaries. The student body frequently calls strikes on various pretexts, for example, because of Sacco and Vanzetti; to request the return to the country of the communistic members who were exiled; and to show sympathy with strikes made by the working classes. As a rule, the leaders of the strikes are students of the lowest scholastic standing. Some of them have been attending the schools for ten or fifteen years. Students, with some exceptions, are only the "tools" in the hands of politicians and of some professors. As a rule, the teachers who are supporters of the reforms have both poor morals and poor knowledge. The students are registered preferably with a privat-dozent who is not strict in demanding attendance at practical work. They demand that their attendance five or ten times be accepted to cover the entire term. The last demand may explain the fact that some of the first year students, who have not finished the study of anatomy, have already finished the practical and clinical work required during the entire course of medicine. The reformists also wish that the fees for studies be completely abolished (they now pay an amount which represents only 20 per cent of the total expense to the university), they wish the examination for admission to be omitted, and they are decidedly opposed to the restriction of the number of students. This state of affairs has created an antagonism between professors and students. If the faculty does not grant the students' claims they immediately call a strike and attack the faculty; and many times the police seem to ignore it. These conditions lower the standards; the clinical work is not continuous; there is no constant contact between professors and students since the attendance is not regular; the subjects are covered in two or three months, especially the month before the examinations; the students have poor notebooks; hospitals are attended by few students, and the students live in an environment of disrespect and disorder. Many of them obtain their medical degrees without having the necessary preparation.

During the election of professors to the faculty, the students act under the influence of either bad professors or young physicians who, not having as yet a good clientele, try to obtain a chair in the faculty, a position as head of a ward hospital, or popularity to gain political positions. To obtain the votes of the students, they offer them anything. It has been said that the triumph of some candidates in some elections has been secured by bribing the students. During the elections the candidates spend large amounts of money, even 20,000 or more pesos (about $17,200); they install electoral booths in houses near the faculty; they give money to students; they rent fifty or sixty automobiles so that they can send for their student friends to vote to support the candidates. Every year there is trouble caused by this state of affairs, which compels the board of directors of the faculties, either partially or as a whole, to resign. The studies are discontinued almost every year during one or two months and then resumed. It is easy for the students to carry on with this system of violence because some of the daily papers help them. Both politicians and members of the government try to win the good will of the students, but this does not help because the students favor them only for the time they are granting their demands. It is hoped that this system may be improved on by means of better teaching given by full time professors, the continuation of research and the restriction of students by careful selection. Trips of students abroad will probably produce a favorable reaction in the student body.

Disturbances Caused by the Students

The recent changes in the personnel of the government gave origin to some student disturbances. The federations of the students requested from the government the repatriation of communistic members who are in exile; they subscribed to the red international mutual fund; they requested that the professors remain in the faculty a certain length of time, after which they should resign without any rights to be reelected; they rejected the new medical curriculum and by-laws. The principal officers of the national government received every day several commissions sent by the student body, but the members of the faculties were not summoned. However, the government approved the statutes presented by the university, indicating approval of the principles embodied and promising to present to congress new by-laws for the universities. Drs. M. R. Castex and Bonorino Udaondo presented their resignations. Dr. B. A. Houssay did not grant a postponement of his examinations and some one put a bomb in his house. The board of directors declared that every council of directors of the school should include three students with the right to vote and to participate in the management of the school. They issued a decree favoring the temporary nomination of professors without any right to be reelected, and they did not permit the new medical curriculum, which the students opposed, to take effect. Thereupon the board of directors of the faculty of medicine resigned and the vice rector of the university assumed the duty of head of the university by order of the government.

Undulant Fever in Argentina

The members of the Comisión Nacional for the study of Brucella infection in Argentina have broadened the scope of their activities in several provinces. Dr. Sordelli, president of the commission, for seven months was ill with the infection. Cases of undulant fever have been found in men in Capital Federal, Mendoza, San Luis, Córdoba, Buenos Aires, Santa Fé, Santiago del Estero, Tucumán, Catamarca, San Juan, Neuquen and Rio Negro; the largest number of cases was found in Mendoza, Capital Federal, Catamarca and San Luis. The presence of the infection was proved by clinical examination, confirmed by serum reactions and cultures. Infection in goats was discovered in isolated ranches in the provinces of Mendoza, San Juan, Córdoba, San Luis and Catamarca, in cows in Buenos Aires, Santa Fé, Entre Ríos, Corrientes, Córdoba, Catamarca, Mendoza, San Luis, Pampa and Neuquen, and in pigs and sheep in Córdoba and Buenos Aires.

Congress of Comparative Pathology Postponed

The Academia de Medicina of Buenos Aires organized a congress of comparative pathology, which was to meet at Buenos Aires during the present year. Topics to be discussed were to be Brucella infection, rabies, leishmaniasis, helminthiasis and plague. It had been decided to invite several foreign speakers. Owing, however, to the general economic crisis, a large part of those invited declined their invitations for the time being. This circumstance compelled the committee of organization of the congress to postpone the date of the congress.

May 10, 1932.

Medicine as a Career

At a recent meeting of the Budapest Postgraduate Association, Dr. Emile Grosz, professor of ophthalmology and president of the International Association for the Eradication of Trachoma, gave an address on medicine as a career. He said that Billroth, in a letter to a friend, whose son intended to become a physician, wrote that he should remember "that the bed of the physician is not one of rose leaves. Competition is growing and the start is difficult. The founding of a family is ever more difficult, and the pleasures of family life are very often disturbed by the practice of medicine. The pleasure of a physician is little, the gratefulness of patients rare, and more rare is the material compensation, but all these should not deter from becoming a physician one who feels the destiny in himself." Billroth added that the feeling of doing one's duties and the rejoicing at having helped others brings the physician contentment and happiness. Today, fifty years later, these words are still true. In the selection of a career, an undoubted influence is family tradition. The sons of physicians often select for their career their father's profession. In Hungary, Koranyi, Bokay, Jendrassik, Hainiss, were physician's sons. Sometimes chance influences the selection of careers. Liebermann, later professor of public hygiene, decided to select medicine as a profession when his father, on being attacked by robbers in a wood, was released because they recognized in him the good physician of the district. Billroth said that a physician, to be able to lend a helping hand to a lot of patients, must possess a fair quantity of knowledge. It is an advantage to a physician that the more he gives up of his knowledge the greater it becomes. The treasure of knowledge of physicians grows in proportion to the outlay; that is, to the help given to others.

How can a young man obtain the knowledge necessary in medical practice, having due regard to the fact that at present the profession is overcrowded and only the fittest can survive? His training starts in the secondary schools. Many lads select medicine who are not endowed with the ideas that can be procured only in the secondary schools. Another requirement is aptness. A young practitioner has to spend several years in hospitals in practical work and while in practice he has to refresh his knowledge by attending postgraduate studies at least once in two years. The Hungarian method of teaching is similar to the German: a good theoretical basis and intensive practical training. It would not be wise to weaken the theoretical education, which is a characteristic of this system; on the other hand, in the second cycle of the studies, which starts with the passing of the intermediary examinations, provision has to be made for adequate practical training as practiced in England and France.

The overcrowding in the medical profession permits raising of the standard. At the end of the first year's study, the unfit have to be strictly sorted out. This is to the interest of the young man as well as to that of the country.

In Hungary, no special examinations have to be passed by those intending to become specialists. This is wrong. At least four years of uninterrupted work in the same field, in recognized clinics or hospitals, ought to be demanded and at the end of this period there ought to be special examinations before the right to be called a specialist is obtained. Sickness insurance offices and state hospitals should employ only specialists who have a special diploma in the respective specialty.

In Hungary the number of physicians exceeds 8,000, which is too many. The situation is rendered more serious by the unfavorable distribution. There are about 4,000 physicians in Budapest alone. The remaining 4,000 are mostly in the towns and cities, while there are more than 2,000 vacancies in villages. In these small villages, physicians are unable to make even a modest living. Some of the physicians are medical officers. There are 29 county, 139 district and 147 city medical officers. In the community health insurance offices throughout the country, about 3,000 physicians are employed. Even so, several thousand physicians are dependent on private practice, which dwindles from year to year and during the economic crisis has almost entirely gone. The number of specialists has increased tremendously. In Budapest, 3,000 physicians call themselves specialists. And the universities still flood the country with new physicians. In the four universities of Hungary, the number of medical students amounts to 2,400 and the number of new graduates is more than 300 yearly. The excess of physicians is large also in other countries. In some countries, entrance to the medical career is subject to limitations; in Hungary there is the percentage normal system, which, of course, will contribute toward a decrease in the number of physicians. The long period of study, the difficulties of making money, will surely reduce the number of entrants. That this natural decrease was not noticeable up to now is due to the fact that all other careers also are overcrowded.

The livelihood of mental workers becomes more difficult from year to year. In spite of this a well trained physician will prosper even if he does not accumulate wealth. In closing, Professor Grosz said that for the disillusionment which one suffers while in practice one is repaid by the feeling of delight in being able to help mankind.

Strike in Hospital Ended

As I wrote before, about seventy young physicians of the Budapest Jewish hospital went on strike because the board of directors refused their demand for a small salary. The strike lasted for about six weeks, causing great inconvenience to the poor patients, who were never before so dependent on gratuitous treatment in the outpatient departments of the Jewish hospital. This fact had the effect that the management of the hospital felt induced to allow to the young doctors, besides full board and residence, 50 pengo (about $9) monthly salary, up to the first of November, when the question of their payment will be definitely settled. The doctors resumed their work, April 12.

Accidents with Arsphenamine Preparations

Dr. Adolf Erdos of Nagyvarad, Transilvania, at a recent meeting of the local medical club, discussed the causes, prevention and treatment of the immediate, the early, and the delayed undesired reactions associated with intensive arsenical treatment of syphilis. He emphasized that the cause may be the toxicity of the drug, caused by broken vials whose contents are oxidized, the method of application, or the intolerance of the patient, or all combined, and that the treatment should take account of the reaction to previous injections, whether the disease is recent, and whether there is any indication of a reaction on the part of the nervous system or viscera. The urine should be examined before every injection, and special caution is necessary if it contains bile pigment, albumin or much sediment. The practice of using big doses (vials containing 4.5 Gm. of neoarsphenamine intended for veterinary purposes), dissolving the whole content in water and distributing it among six to nine patients, though economical, is dangerous. The injection should always be made extremely slowly, while watching for the least untoward sign. The physician, realizing his responsibility, should keep the record of these cases written in full to date, and a solution of epinephrine and of thiosulphate should always be at hand to combat any sign of intolerance.

Marriages

CLARENCE WILLIAM PEAKE, Baltimore, to Miss Mary *Elizabeth Bouis of* Mount Washington, June 15.

SAUL KENNETH POLLOCK, Wauwautosa, Wis., to Miss Luby Myrtle Bragarnick of Milwaukee, May 22.

ANTHONY P. MURRAY, Girardville, Pa., to Miss Mary A. Noonan of Mahanoy City, June 18.

JOHN JAIRUS BERNHARD, Allentown, Pa., to Miss Hilda Susan Miller of Bangor, June 11.

JAMES O. NALL, Murray, Ky., to Miss Florence Phillips of Meridian, Miss., June 4.

RUSTIN MCINTOSH, New York, to Miss M. Millicent Carey of Baltimore, June 25.

PAUL HIGBEE, Sullivan, Ind., to Miss L. Gertrude De Vine in Chicago, May 22.

Deaths

Michael Osnato ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1906; member of the American Neurological Association, American Psychiatric Association and the Association for Research in Nervous and Mental Diseases; clinical professor of neurology at his alma mater and professor at the New York Post-Graduate Medical School; consulting neurologist to the Central Islip (N. Y.) Hospital, Manhattan State Hospital, St. Joseph's Hospital and Columbus Hospital; director of the department of neurology, Post-Graduate Hospital; aged 45; died, June 15, in Berlin, Germany.

Norman McLeod Heggie ⊕ Jacksonville, Fla.; University of Maryland School of Medicine, Baltimore, 1902; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; served during the World War; oculist and aurist to St. Vincent's Hospital and the Riverside Hospital, where he died, May 9, of coronary thrombosis and arterial hypertension.

Eley Ebert Perisho, Streator, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897; councillor of the second district and member of the Illinois State Medical Society; president and formerly secretary of the La Salle County Medical Society; aged 57; on the staff of St. Mary's Hospital, where he died, May 28, of septicemia.

George Keyser Angle, Albuquerque, N. M.; Bellevue Hospital Medical College, New York, 1891; member of the House of Delegates of the American Medical Association in 1910; member and past president of the New Mexico Medical Society; served during the World War; aged 65; died, May 8, of angina pectoris.

Francis Roe Benham ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1901; formerly instructor in clinical obstetrics at his alma mater; on the staff of the Onondaga General Hospital; aged 55; died, May 28, of gastric hemorrhage, duodenal ulceration and cirrhosis of the liver.

John Parmenter, Geneva, N. Y.; University of Buffalo School of Medicine, 1883; member of the Medical Society of the State of New York and the American Surgical Association; formerly professor of clinical surgery at his alma mater; bank president; aged 70; died, June 1, of intestinal obstruction.

Byron Fuller Barker ⊕ Bath, Maine; Jefferson Medical College of Philadelphia, 1896; president of the Sagadahoc County Medical Society; fellow of the American College of Physicians; aged 59; on the staff of the Bath City Hospital; where he died, April 29, of septic peritonitis.

Winchester C. Smith, Williston, S. C.; College of Physicians and Surgeons, Baltimore, 1879; member of the South Carolina Medical Association; aged 77; died, May 28, in the University Hospital, Augusta, of chronic cholecystitis, cholelithiasis, thrombophlebitis and gangrene.

Joseph M. Tribble, Lithonia, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1895; formerly professor of the practice of medicine and diseases of children at his alma mater; at one time mayor of Lithonia; aged 67; died, May 20, in a hospital at Atlanta.

Frank Edward Dean ⊕ Bennington, Vt.; Albany (N. Y.) Medical College, 1915; president of the Bennington County Medical Society; on the staff of the Henry W. Putnam Memorial Hospital; aged 40; died, May 13, of chronic myocarditis and angina pectoris.

Chase P. Ambler ⊕ Asheville, N. C.; Western Reserve University Medical Department, Cleveland, 1889; past president of the Buncombe County Medical Society; medical director and owner of the Ambler Heights Sanitarium; aged 66; died, June 5, of pulmonary edema.

George W. Rossman, Ancram, N. Y.; Albany (N. Y.) Medical College, 1866; member of the Medical Society of the State of New York; past president of the Columbia County Medical Society; aged 91; died, June 11, in Hudson, of chronic endocarditis.

Charles Anthony Beck, Wilmington, Del.; University of Maryland School of Medicine, Baltimore, 1900; member of the Medical Society of Delaware; formerly secretary of the board of health; aged 58; died, May 19, of carcinoma of the gallbladder.

Malcolm Douglass, Jr., Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1887; member of the Medical Society of the State of Pennsylvania; aged 67; died, May 31, in the Temple Hospital, of cerebral hemorrhage.

John Harvey Copenhaver ⊕ Bellflower, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; on the staff of St. Joseph's Hospital, Bloomington; aged 55; died, April 26, of pyelonephritis.

Roy Earl Brown ⊕ Washington C. H., Ohio; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; past president of the Fayette County Medical Society; aged 55; died, June 1, of heart disease.

Leo Charles McDermott, Chicago; Georgetown University School of Medicine, Washington, D. C., 1913; on the staffs of the John B. Murphy Hospital and St. Joseph's Hospital; aged 43; died, May 30, in Madison, Wis., of cerebral hemorrhage.

Roger A. Smith, Goldsboro, N. C.; Vanderbilt University School of Medicine, Nashville, Tenn., 1879; member of the Medical Society of the State of North Carolina; on the staff of the Goldsboro City Hospital; aged 73; died, May 23.

James Henry Somerville, Jr. ⊕ Tuscaloosa, Ala., Medical College of Alabama, Mobile, 1906; past president and secretary of the Tuscaloosa County Medical Society; on the staff of the Druid City Hospital; aged 49; died, April 20.

Julian Birch Trotter, Rouses Point, N. Y.; University of Buffalo School of Medicine, 1927; member of the Medical Society of the State of New York; aged 31; died, May 27, of injuries received in an automobile accident.

Etta May Hadley-Judd, Lynchburg, Va.; Woman's Medical College of Pennsylvania, Philadelphia, 1895; member of the Medical Society of Virginia; aged 61; died, March 30, of injuries received in an automobile accident.

Emil Christensen ⊕ Two Rivers, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1896; on the staff of the Two Rivers Municipal Hospital; aged 62; was found dead in bed, May 26, of cerebral hemorrhage.

Cornelius J. Phillips ⊕ Chicago; Rush Medical College, Chicago; 1890; aged 73; on the staffs of the German Deaconess Hospital and St. Bernard's Hospital, where he died, June 6, of acute myocarditis and arteriosclerosis.

Jefferson Bostwick Councill, Salisbury, N. C.; College of Physicians and Surgeons, Baltimore, 1885; member of the Medical Society of the State of North Carolina; aged 76; died, April 21, of lymphosarcoma.

Russell D. Toben, Bloomfield, Iowa; Keokuk (Ia.) Medical College, 1897; member of the Iowa State Medical Society; secretary and past president of the Davis County Medical Society; aged 65; died, April 13.

Asher Tunis Applegate, Englishtown, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1869; member of the Medical Society of New Jersey; for thirty-five years mayor; aged 85; died, May 31.

David Wendell Philips, Victor, Iowa; Columbus (Ohio) Medical College, 1885; also a druggist; formerly mayor of Victor and president of the school board; aged 73; died, May 16, of cerebral hemorrhage.

James F. Kline, Anoka, Minn.; University of Minnesota College of Homeopathic Medicine, Minneapolis, 1893; aged 71; died, May 19, of carcinoma of the rectum, pneumonia and cerebral hemorrhage.

⊕ Indicates "Fellow" of the American Medical Association.

Joseph Cook Wallace ⊕ Buffalo; Hahnemann Medical College and Hospital of Philadelphia, 1903; on the staff of the Millard Fillmore Hospital; aged 53; died, April 22, of cerebral hemorrhage.

Eugene Hubbell, St. Paul; Hahnemann Medical College and Hospital, Chicago, 1883; aged 77; died, April 20, in the West Side General Hospital, of hemorrhage of the urinary bladder and uremia.

James Muir, New Buffalo, Mich.; Drake University Medical Department, Des Moines, 1897; aged 61; died, May 15, in a hospital at Benton Harbor, of injuries received in an automobile accident.

Alma Lapham Williston, Phillipsburg, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1881; aged 79; died, May 6, in the Warren Hospital, of carcinoma of the stomach.

William Lenox McWilliams, Miami, Okla.; University of Louisville (Ky.) School of Medicine, 1891; formerly mayor and postmaster of Miami; aged 66; died, April 6, of angina pectoris.

Asa Price Martin, Cullman, Ala.; Chattanooga (Tenn.) Medical College, 1897; member of the Medical Association of the State of Alabama; aged 59; died, May 27, of organic heart disease.

Charles G. Van Tilburg, Hayesville, Ohio; Cleveland Medical College, Homeopathic, 1894; formerly member of the county board of health; aged 66; died, April 20, of heart disease.

Frank Harvey Allen ⊕ Staples, Minn.; Rush Medical College, Chicago, 1894; formerly mayor and member of the board of education; aged 61; died, May 2, of organic heart disease.

Zachary Taylor Young, New Orleans; Tulane University of Louisiana Medical Department, New Orleans, 1911; member of the Louisiana State Medical Society; aged 47; died, May 9.

Charles M. Chamlee, Adairsville, Ga.; University of Georgia Medical Department, Augusta, 1899; aged 57; died, May 11, in the Piedmont Hospital, Atlanta, of carcinoma of the lungs.

Arthur Bremken, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; aged 57; died, May 30, of an overdose of chloroform.

Colin A. Stewart ⊕ Bay City, Mich.; Detroit College of Medicine, 1900; on the staffs of the Bay City General Hospital and the Mercy Hospital; aged 55; died, May 1, of heart disease.

Masakichi Shinohara ⊕ Los Angeles; Okayama Medical School, Okayama, Japan, 1906; aged 48; died, May 27, in the Southern California Japanese Hospital, of cirrhosis of the liver.

Samuel L. Burton, Richmond Hill, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1900; aged 58; died, March 2, in St. Petersburg, Fla., of pneumonia.

William P. Love, Flatrock, W. Va.; College of Physicians and Surgeons, Baltimore, 1884; aged 70; died, May 10, in the Ball Memorial Hospital, Muncie, Ind., of abdominal carcinoma.

William Ruoff, San Diego, Calif.; University of Pennsylvania School of Medicine, Philadelphia, 1892; aged 63; died, May 21, in the U. S. Naval Hospital, of pulmonary tuberculosis.

William H. McKenna, Austin, Minn. (licensed by law of exemption); aged 88; died, April 26, of coronary occlusion, chronic myocarditis, bronchopneumonia and cardiac asthma.

John Wade, Baltimore; College of Physicians and Surgeons, Baltimore, 1902; aged 68; died, June 2, in Towson, Md., of bronchopneumonia, arterial hypertension and nephrectomy.

Lelon Potter Botsford ⊕ Kenmore, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1910; aged 49; died, March 21, of coronary thrombosis.

Francis N. Drake, San Diego, Calif.; Jefferson Medical College of Philadelphia, 1877; aged 81; died, April 16, of carcinoma of the bladder and strangulation of the bowels.

Frank Albert Bagley, Weston, Mo.; University of Illinois College of Medicine, Chicago, 1928; aged 29; died, May 6, in the Research Hospital, Kansas City, of heart disease.

Thomas A. Russell, Spokane, Wash.; Barnes Medical College, St. Louis, 1895; member of the Washington State Medical Association; aged 61; died, May 15, of heart disease.

Joseph Arthur Wolcott, Watertown, Mass. (licensed, Massachusetts, years of practice); medical superintendent of the Watertown Hospital; aged 76; died, May 17.

E. L. Rhodes, Lincoln, Mo.; Joplin (Mo.) Medical College, 1879; past president of the Missouri State Medical Association; bank president; aged 81; died, May 7, of senility.

Alfred Rufus Crain, New York; University of Buffalo School of Medicine, 1881; aged 75; died, May 24, at St. Luke's Hospital, of chronic nephritis and myocarditis.

Judson D. Irwin, St. Louis; Rush Medical College, Chicago, 1878; formerly coroner of St. Louis; aged 79; died, April 20, of carcinoma of the pelvic colon.

John W. Crabtree, Harrisonville, Mo.; Kansas City (Mo.) Medical College, 1896; aged 62; died, April 27, of septic infection of the bladder and chronic cystitis.

Mari Hendrik Philip Panhorst, Jonesboro, Tenn. (licensed, Tennessee, 1889); member of the Tennessee State Medical Association; aged 84; died, April 24.

William Alvin Belt, Kenton, Ohio; Medical College of Ohio, Cincinnati, 1886; member of the Ohio State Medical Association; aged 69; died, May 14.

Thomas Andrew Cravens, Colorado Springs, Colo.; Long Island College Hospital, Brooklyn, 1874; aged 84; died, May 7, of arteriosclerosis and endocarditis.

Bureau of Investigation

LAMBERT CHEMICAL COMPANY, INC.

The Exploiters of Phos-Phane Would Have Physicians Underwrite Their Financial Success

A number of letters have been received during the past six months from physicians who have been approached by solicitors, or alleged solicitors, for the Lambert Chemical Company, Inc., of Washington, D. C. (This company is not to be confused with the Lambert Pharmacal Company of St. Louis.) A Georgia physician wrote:

> "A representative from the Lambert Chemical Company of Washington, D. C., has just left my office, soliciting the use of a preparation known as Phos-Phane. He stated that they were making a proposition to the profession that the doctor specify this particular form, that a drug store recommended by him would stock it, and that they would then, at the end of a given time, send a check of $6.00 for a carton of the drug as used. He would also be given shares of stock in the company."

From a Florida physician came this letter:

> "Please advise if the Lambert Chemical Company, Inc., Washington, D. C., makers of Phos-Phane, is a reputable concern; if the American Medical Association has ever endorsed Phos-Phane for any particular use, and have you heard of this company's giving doctors stock in the company for endorsing their product."

From an Indiana physician came this:

> "The Lambert Chemical Company, Inc., of Washington, D. C., is putting out a product called Phos-Phane, a laxative, which the company claims is accepted by the Council of the A. M. A. A representative is going around with signed endorsement from the chemistry department of the A. M. A. Please inform me if the representations of the company are genuine and ethical."

Two telegrams from Florida physicians read, respectively:

> (1) "Dr. R. E. Bryant from Virginia here trying give physicians stock Lambert Chemical Company, District of Columbia, provided they sign note which is to be paid by druggist, who would sell Phos-Phane, which Bryant would send druggist. He has your letter endorsing his plan. Is it genuine?"
>
> (2) "Lambert Chemical Company, Washington, D. C., offering fifty dollars free stock in their company to Miami doctors prescribing their preparations. Doctors sign trade acceptance coupon, agreeing to pay for preparations. Many A. M. A. members falling for scheme."

A physician in North Carolina wrote within the last week or two:

> "I am sending the following report of my experience with the Lambert Chemical Company, Inc., of Washington, D. C., with recommendation that the company be investigated. Sometime in November, 1931, a salesman from the above company approached me in my office in regard to a product, Phos-Phane. His proposition was something to this effect: That I sign for a certain number of bottles to be placed in any drug store that I might choose and that if, at the end of a certain time, I had prescribed sufficient Phos-Phane for the entire stock to have been sold, I be given one hundred shares in the company producing Phos-Phane. If I had not prescribed sufficiently to use up the supply of Phos-Phane I was to pay the difference.
>
> "Needless to say, I refused his proposition. A short time later, I received a letter from the Lambert Chemical Company of Washington, D. C., stating that their salesman had placed an order for Phos-Phane in my name, that he was a new man, and that, although they felt sure he was to be trusted, they would like to know just how this order was obtained. My answer to this letter was that there had been no order.
>
> "May the first of this year, I received a notice from my bank that a note to Lambert Chemical Company for $96.00 was due for payment on May 16th. On investigation, this proved to be a 'Trade Acceptance' from the Lambert Chemical Company of Washington, D. C., with my signature forged. It was presented to the Citizens Bank and Trust Company of Southern Pines, N. C., through the National Metropolitan Bank of Washington, D. C."

First let it be said that "Phos-Phane" has not been accepted by the Council on Pharmacy and Chemistry for "New and Nonofficial Remedies" nor, of course, has any endorsement of Phos-Phane been given by any officer or employee of the American Medical Association.

In a printed circular on Phos-Phane, the following vague information is given regarding its alleged composition:

> "It is a clear, slightly yellowish, concentrated solution of a sodium phosphate which differs from the normal phosphate and contains in suitable form a particular salt of sodium phosphate which is not precipitated by cold water."

A letter was written to the Lambert Chemical Company, Inc., by the Director of the A. M. A. Chemical Laboratory, asking for a qualitative and quantitative statement regarding the composition of Phos-Phane. The letter was addressed to the company at Washington, D. C., no street address being given, because, at that time, no street address was known. The letter was returned by the Post Office Department marked "Unclaimed" and "Not in the Directory." A month later, another letter was written to the Lambert Chemical Company, this time addressed to 1415 K Street, N. W., Washington, D. C., this address having been sent to the American Medical Association by a Washington physician. This letter also the postal authorities returned marked "Unclaimed." Two months later, a third letter was addressed to the Lambert Chemical Company, also at 1415 K Street, N. W. This time, it reached the concern, which had apparently moved to 511 Eleventh Street, N. W., Washington, D. C. The company replied that its preparation was "not secret in composition" and added:

> "It contains Disodium Phosphate U. S. P. free from effloresced salts, Phosphoric Acid U. S. P. and distilled water. The amount of Disodium Phosphate is eighty-five per cent."

Photographic reproduction (greatly reduced) of three blank forms used by the Lambert Chemical Company, Inc., in the sale of its preparation, Phos-Phane. The top blank, described as a "Trade Acceptance," is, as will be noted, essentially a promissory note that is to be signed by the physicians. The second blank is an agreement signed jointly by the physician and the local druggist, while the third (and lower) blank is an agreement on the part of the Lambert Chemical Company to give to the physician who has bought and prescribed Phos-Phane so many shares of stock, according to the number of dozen bottles of Phos-Phane purchased. Whether stock in the Lambert Chemical Company, Inc., has any value over and above that of the paper on which it is printed is probably a matter that only the future can decide. It would seem, however, that the Lambert Chemical Company, Inc., is playing a game of heads-I-win, tails-you-lose with the physicians.

A letter written by the Lambert Chemical Company, Inc., last August, stated that the company had the following officers and directors:

Eugene D. Crouse, Washington, D. C., President.
Dr. J. A. Rucker, Bedford, Va.
Dr. E. L. Johnson, Bedford, Va.
Dr. D. E. Remsberg, Roanoke, Va.
W. Harvey Woods, Salem, Va.
Harry F. Lambert, Lynchburg, Va.

Dr. J. A. Rucker, in answer to an inquiry put to him by the Bureau of Investigation in May of this year, replied that he was not a director nor connected in any official way with the Lambert Chemical Company and never had been, but that he does have a few shares of its stock. Doctor Rucker expressed the opinion that the company has "an excellent preparation." Dr. E. L. Johnson, who was also written to, replied that he had stock in, and is a director of, the company, and that he found "Phos-Phane is a very efficient and ethical preparation." Dr. D. E. Remsberg wrote that he was one of the directors, but stated that he had never attended any of the directors' meetings. The Lambert Chemical Company is incorporated in Delaware. The active promoter of the concern is said to be Eugene Crouse.

The company's method of doing business is made fairly clear from the letters and telegrams that have been quoted. We are reproducing in miniature with this article some of the blank forms used by the Lambert Chemical Company in getting physicians, practically, to underwrite the sale of its preparation, Phos-Phane. The most important of these forms is the "Trade Acceptance" blank. This, it will be noticed, is to be signed by the "acceptor," who is the physician. When it has been so signed, this blank becomes for all intents and purposes, a promissory note, by which the physician is buying so many bottles of Phos-Phane, agreeing to pay for them, and helping to get them placed in the local drug store on consignment.

Aside altogether from the dubiousness of the transaction from a commercial point of view, it must be quite obvious that any physician that goes into this scheme is violating one of the fundamental tenets of his profession. No medical man with a proper appreciation of his responsibilities will be financially interested in the exploitation of medicinal agents that he may be called upon to prescribe for his patients.

Correspondence

SODIUM THIOCYANATE (RHODANATE) IN NARCOTIC ADDICTION

To the Editor:—There has been disseminated, largely through the lay press, considerable publicity concerning the use of sodium rhodanate (thiocyanate), as a "cure" for drug addiction. Most of this has emanated from that branch of the department of chemistry of Cornell University under Prof. Wilder D. Bancroft. The claim is made that this drug is a dependable and efficient "cure" for morphinism and that it also exerts a favorable influence in alcoholism, acute and chronic, and in some of the psychoses.

The Tompkins County Medical Society has watched this development with considerable interest and has observed the widespread publicity given this drug to the lay press, with no little concern. It thus takes this opportunity to lay before you its opinion on some phases of this problem.

As is well known, in any inquiry regarding the value or lack of value of any therapeutic device or agent for the relief of human illness it is essential that control tests be conducted at the same time or under similar conditions as the experimental tests. These may be accomplished by utilizing nothing in the control procedures or by the use of agents that up to the time of the experiments have been known to influence favorably the given conditions. In the series of experiments with drug addicts in Ithaca, no controls of any type were used. It is well established that bromides and chloral, bromides and codeine, or codeine alone tend to lessen the intensity of the withdrawal phenomena in the treatment of drug addiction; yet these drugs were not used in control cases so as to test the relative efficacy of these compared with sodium rhodanate. It is maintained that this was a grave experimental oversight.

Sodium rhodanate has been freely used by its proponents in numerous disease states despite the fact that the pharmacology of it is, as yet, imperfectly understood. That this free administration is not without danger is attested by the fact that one out of ten patients receiving this drug died an inexplicable death. An autopsy failed to reveal any real cause for the sudden demise. The preagonal condition suggested a central origin.

As with many therapeutic innovations, the original experiment with a single case was a success. Yet the medical society has learned from the superintendent of the New York State Hospital at Willard that the test individual, a morphine addict, had been cured six times previously at that institution. Great publicity followed this single success, with many unpleasant repercussions. Regarding this incident, the Medical Society of Tompkins County, N. Y., feels that to herald to the world as a cure a substance that is apparently successful in one case is unscientific, even though this demonstrates the correctness of the hypothesis regarding its action.

That the hypothesis concerning the action of sodium rhodanate on nervous tissue colloids (Bancroft, W. D., and Rutzler, J. E., Jr.: Colloid Chemistry of Nervous Systems, *J. Phys. Chem.* **35**:1185 [May] 1931) is worthy of consideration and that the drug may have some merit, the members of the medical society would be foolish to deny. Yet the worth-while features, if any, are lost in a maze of enthusiastic claims made for this new therapeutic scheme. The society feels that this whole problem should have been approached with extreme caution and in a highly critical manner and that the usefulness or lack of value of sodium rhodanate in drug addiction should first have been demonstrated in large institutions prior to any suggestion of publicity. The tests should have been conducted by trained and experienced investigators with suitable controls, under strict supervision, and only after the study of a large series of cases over a long period of time should any publicity of any kind been given out. Of the three Ithaca investigators, Prof. W. D. Bancroft, John E. Rutzler, M.S., and Robert S. Gutsell, M.D., not one has had sufficient contact with cases of drug addiction to warrant credence being placed in their observations on this type of case.

It is of interest to state at this time that the medical society has knowledge of more than a hundred cases of drug addiction treated with sodium rhodanate without success. The investigators concerned were unanimous in their declarations that this drug had little or no effect on the withdrawal signs and symptoms and was in no sense a "cure." Regarding the use of sodium rhodanate in alcoholism, the medical society contends that no data have been brought forward to prove any favorable influence in this condition. The occasional marked depressor action of large doses of the rhodanate may prove a contraindication.

To maintain, as did Professor Bancroft before the International Narcotic Education Association in New York City, that sodium rhodanate can be used as a "cure" for drug addiction demonstrates an ignorance of the basic psychobiology of this "maladaptation." Only those who have had long experience with this type of psychologic variant are in a position to judge the possible value of a so-called cure.

The Tompkins County Medical Society of New York has approved this communication, which it submits as a protest against the intensive publicity involving the "cure" of drug addiction by means of sodium rhodanate and to report that there are numerous physicians in touch with some of the details of past experiments with the rhodanate who feel that far too much is claimed for this substance. So far as can be determined at present, there is no magic efficacy nor convincing beneficial effect of sodium rhodanate in disturbances of nervous system colloids in various disease states and the case for the drug remains to be proved.

Special Narcotic Committee of the
Tompkins County Medical Society.

FRACTURE OF THE NECK OF THE FEMUR

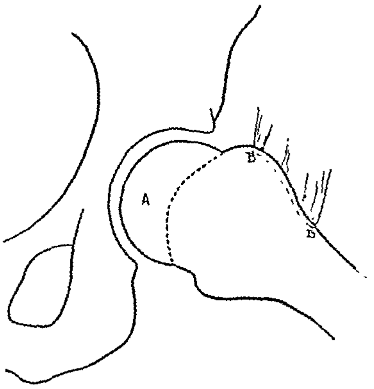
To the Editor:—I note that Dr. Magnuson, in his instructive paper on repair of ununited fracture of the neck of the femur (THE JOURNAL, May 21, p. 1791) employs what he calls the Brackett operation.

The operation is, in substance, removal of the trochanter at its base, transplanting it to the outer border of the shaft, and inserting the denuded neck into a hollowed out head. This procedure has already been described by Allison and Henderson under the same misleading title.

Brackett's operation is entirely different both in principle and in design. It was based on the proposition that the nutritive capacity of the trochanter was greater than in the neck fragment. He therefore removed the muscular attachments from the apex of the trochanter and apposed its rounded upper and inner extremity to the hollowed out head. Brackett's title was "operative transplantation of the femoral head to trochanter."

It should be evident, therefore, that one cannot perform a Brackett operation if the trochanter is transplanted to the shaft.

Dr. Magnuson contrasts the Whitman and the "Brackett" operation, as if the only distinction between the two were the removal or retention of the femoral head.



Brackett's illustrative diagram, from his second paper, for comparison with illustrations in the paper of Dr. Magnuson: *A*, head in position on upper and inner surface of trochanter; *B*, *B*, muscles reattached at lower level on shaft of femur.

The purpose of the reconstruction "Whitman" operation is to restore the capacity for locomotion. The removal of the trochanter at its base provides a new bearing surface or improvised neck, while the transplantation of the trochanter with its attached muscles to a lower level on the shaft restores voluntary control of the limb, thus justifying the title.

It was devised for a class of cases in which the destructive process was advanced and in which the neck was represented only by a shallow, irregular rim of cortical substance enclosing fibrofatty tissue.

In Dr. Magnuson's reported cases, the neck fragment is of sufficient length to permit an approximation to the head after the trochanter has been removed, which permits 45 degrees of abduction. Even in cases of this type, as in all other operations in which the result is dependent on union of the fractured surfaces, there is besides the uncertainty of repair the danger of subsequent degeneration of the cartilage and progressive arthritis deformans.

The typical reconstruction operation has the advantage that it assures to the disabled patient the capacity for weight bearing and fair control of the limb within a definite period.

Since the purpose of this communication is to correct an error in nomenclature which seems to be firmly established, I append Dr. Brackett's diagram for comparison with Dr. Magnuson's illustrations.

For those who care to verify references, it may be stated that Dr. Brackett's description of his operation was published in the *Boston Medical and Surgical Journal*, Sept. 13, 1917. A second paper on the subject appeared in the same journal, June 4, 1925. This was in substance an account of the later results in the original case. No other reports of the Brackett operation have come to my notice.

It is evident that Dr. Magnuson has never performed a Brackett operation. He has, however, presented an interesting question—whether the approximation of the neck to the hollowed out head, made practicable by the reconstruction procedure, may not be more effective in assuring union and improved function than bone grafting or spiking.

ROYAL WHITMAN, M.D., New York.

ANOTHER UNPUBLISHED BEAUMONT LETTER

To the Editor:—This letter from William Beaumont was written to his cousin, Andrew Beaumont, at that time a member of Congress from Pennsylvania. Another letter to him was published in THE JOURNAL, Aug. 22, 1925, page 632. This letter, like the previous one, was presented to the Beaumont Medical Club by André A. Beaumont of Wilkes-Barre, Pa., the grandson of Andrew Beaumont. It is deposited in the Yale University Library.

J. E. LANE, M.D., New Haven, Conn.

Mem° for my Hon. Cous.

Hold fast y^r political integrity against the combined attack of wealth, power, fraud, flattery, force or fear—the world, the flesh or the devil.

Remember y^r friend & be assured of his most cordial esteem & sincere respect for yourself and family.

Let him hear from you often—attend to his little interests at the great national metropolis and be assured of his fervent prayers for your final success in all your undertaking—moral, political, professional and scientific—domestic, agricultural and hymenial—at home and abroad—in public and private—in prosperity and adversity—may good health attend and shower its choicest blessings on your family & friends.

8th June 1834.

GLYCINE OR GLYCOCOLL

To the Editor:—The favorable results obtained by Drs. Milhorat, Techner, and Thomas (*Proc. Soc. Exper. Biol. & Med.* **29**:609, 1932) in the treatment of progressive muscular dystrophy with glycine will undoubtedly lead to a more extensive use of this compound in therapy. It seems therefore necessary at this time to call attention to the fact that glycine, also called glycocoll, should not be confused with the photographic developer which is sold under the trade name of glycin. This compound is chemically *p*-hydroxyphenylaminoacetic acid and is distinctly poisonous.

ARMAND J. QUICK, M.D., New York.
Department of Surgical Research, Cornell
University Medical College.

THE SANITARY SURVEY OF KANSAS CITY

To the Editor:—Referring to the book review on this subject in THE JOURNAL, May 14, it seems to me that the criticism published therein is quite inconsistent with the fact that we have received second highest honorable mention in the health contest for cities with a population of between 400,000 and 500,000. I note the article states that under food control is grouped the control of rabies, which is not true, and it also states that cutting weeds is not a matter of sanitation. We regard it as such for the reason that vacant lots grown up with weeds which decay and furnish a place for dumping of insanitary matter result usually in an insanitary condition unless kept free of weeds. It is also a menace to the health of the residents in the vicinity of such places on account of hay fever and asthma, mosquito breeding, and so on.

Every branch of our service is under a separate heading, directly under the commissioner of inspections, a division of the health department, which is divided into the subdivisions of and controlled by a chief sanitary inspector and inspectors, a chief food inspector and inspectors, a chief dairy inspector and inspectors, a chief barber inspector and inspectors, a chief housing inspector and inspectors, and a veterinarian, who is in charge of the immunization of dogs. We have another division under the commissioner of child hygiene and communicable diseases, a division of hospitals and the division of records and vital statistics.

Calvin L. Cooper, M.D., Kansas City, Mo.
Director of Health.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF SYPHILIS

To the Editor:—A man, now 35 years of age, had a penile ulcer thirteen years ago. One or two intravenous treatments healed it. That was the only treatment. He married twelve years ago and now has two children, aged 6 and 8 years. To date he has "been well." Three months ago I took a blood test in a routine physical examination and found the Wassermann and the Kahn reaction four plus. Since then he has had ten intramuscular injections of mercury and ten intravenous injections of neoarsphenamine. I am now starting on a course of ten injections of sulpharsphenamine bismuth. All the time he has had mercury and iodides orally. Have you any suggestions as to future treatment? What should be done in the cases of the children, who seem healthy? Please omit name.

M.D., Ohio.

Answer.—In answering this inquiry, it will be necessary to divide it into two portions: first, the treatment of the father, and, second, the treatment of the offspring. Of course, the wife must be considered as well.

As far as the father is concerned, little evidence is furnished as to his true condition. Nothing is said as to an involvement of the cardiovascular system or as to evidence of involvement of the central nervous system. Moreover, a lumbar puncture has not been done. These details should all be gone into carefully in a patient of this sort, for only too often the four plus Wassermann and Kahn test in a patient of this type may not only indicate a positive serologic reaction but also be another evidence of a serious involvement of the cardiovascular system or of the central nervous system. Therefore, it is rather difficult to answer the correspondent as to the treatment indicated in a patient of this type. If he seems to be in good condition from the standpoint of his heart and aorta it would be advisable, having finished the course of ten injections of neoarsphenamine, to give him a course of ten intramuscular injections of a bismuth salt, as he had ten injections of mercury in the beginning. Potassium bismuth tartrate or sodium bismuth tartrate, from 0.1 to 0.2 Gm., or bismuth salicylate, 0.13 Gm., given once a week for a period of ten to twelve weeks, may be tried; this with another series of neoarsphenamine injections given once a week, each of 0.6 Gm., for a total of ten injections. If the patient stands this treatment well and if his kidneys show no evidence of irritation, we would be almost inclined to follow up this course of neoarsphenamine injections with a further course of bismuth injections intramuscularly and then again another course of neoarsphenamine injections. Throughout this therapy it would be well for the patient to take potassium iodide in 0.5 Gm. doses internally three times a day. Moreover, a serologic examination should be made at the end of each course of injections of the neoarsphenamine and of the bismuth. What further treatment would be indicated in this patient will depend much on whether he has an involvement of the central nervous system or of the cardiovascular system. In this connection, the correspondent would do well to consult Venereal Disease Information, volume 10, number 2, Feb. 20, 1929, entitled "The Management of Syphilis in General Practice."

If the children have syphilis, the mother also will be affected. It is well known that the older a syphilis is, the less danger there is of its being transmitted. This applies even when the patient has had no treatment at all. The French syphilologist Fournier was the first one to call attention to this fact. So there is a possibility that neither the mother nor the children will be affected, as the first child was born five years after the infection. The difficulty arises from the fact that he was married one year after the infection, and it would seem almost impossible for his wife not to contract syphilis, unless most stringent precautionary measures were taken for a period of years, and, naturally, if the wife contracted the disease and received no treatment, there would certainly be a good chance of the children having the disease likewise. It is easier for the disease to be transmitted by way of placental blood than it is for a case of old syphilis in a husband to be transmitted to the wife. The placental blood gives a more intimate and freer opportunity for circulating spirochetes to be transmitted to the child. We would advise that a searching physical examination be made of the wife and children, including serologic tests, lumbar puncture, and, on the mother as well, roentgen examination of the heart and the aorta. Instead of depending on one serologic test, it would be better to have two or three and insist that not only is the Wassermann test done but also one of the good precipitation tests, for example, the Kahn, Kline or Hinton test, as well. If the mother and the children are found to be affected, much the same type of treatment could be recommended as in the case of the father, though naturally the dosage employed in the children would have to be modified somewhat. If there is an involvement of the central nervous system in the case of the father, the mother or the children, naturally this is a problem in itself and could be better answered after knowing the type of involvement.

SODIUM THIOCYANATE (RHODANATE)

To the Editor:—I should appreciate it if you can tell me what sodium rhodanate is. Is it a new chemical compound? I have read a few newspaper articles on its being experimented with as a treatment for drug addicts. I am not able to find it in any textbook on chemistry or materia medica I have.

M.D., Florida.

Answer.—Sodium rhodanate is the obsolescent name for sodium thiocyanate (sulphocyanate), a drug producing actions resembling those of the iodides. Statements concerning its actions and uses may be found in standard works of reference such as Sollmann's Manual of Pharmacology, edition 4.

Publicity has recently been given to the work of Wilder D. Bancroft, professor of physical chemistry at Cornell University, and his associates, who last year reported to the National Academy of Sciences on animal experiments in which they had used sodium thiocyanate to prevent withdrawal symptoms in morphine addiction. The theory of these investigators is that the drug combats by "peptization" the "agglomerated" colloids which they hold accompany certain kinds of insanity or the use of certain drugs. Their work has not prompted any medical investigator to publish reports of confirmatory clinical trial, and according to *Science* (May 13, 1932, p. 12 of supplement) preliminary investigation by the U. S. Public Health Service has failed to confirm the claims of Bancroft and his associates.

Although the published reports of these investigators do not appear to make the claim that sodium thiocyanate is a "cure" for morphine addiction, in the *Chemical Bulletin* of the Chicago section of the American Chemical Society for May, 1932, Professor Bancroft is reported as having stated that he knew of a morphine addict who had cured himself by the use of sodium rhodanate without assistance or advice from any one else. Any one with even a moderate knowledge of the treatment of drug addicts must know that an apparent single "cure" does not constitute evidence.

RADIUM EFFECTS ON BRAIN TISSUE

To the Editor:—What is the relative susceptibility of brain tissue to radium rays? Are there any sequelae such as epilepsy, mental retardation or deficiencies known to follow radium therapy about the head? Would from three to five (with 20 mg. of radium) exposures of from one to two hours, screened in the usual way and applied to the forehead of an infant, aged 4 months, have any injurious effect on the brain?

J. H. Murray, M.D., Stronghurst, Ill.

Answer.—Normal brain tissue is quite resistant to the action of radium and roentgen rays. Cases of damage to the brain by a normal dose of radium have not been recorded; i. e., any dose that does not cause permanent damage to the skin. Sequelae from x-ray or radium treatments over the skull externally have not been noted. The correspondent does not state his dose completely (distance, filter, and area treated), but as far as can be judged he is well within the limits of any injury to the skin and would, therefore, come within the foregoing statement. The subject has been discussed by:

Williamson, C. S.; Brown, R. O., and Butler, J. W.: Effects of Radium on Normal Brain Tissue, *Surg., Gynec. & Obst.* **31**: 239 (Sept.) 1920.

Pancoast, H. K.: Treatment of Brain Tumors by Radiation, *Am. J. Roentgenol.* **9**: 42 (Jan.) 1922.

EXFOLIATIVE DERMATITIS AFTER NEOARSPHENAMINE

To the Editor:—I have a patient to whom I have given six or seven doses of neoarsphenamine. She had a four plus positive Wassermann. The only objective symptom she seems to have was an enlarged sternal end of the clavicle, and definite irregular macules, occasionally found here and there over the body. About three days after the last injection she came in with her left ear swollen, and the face and arms erythematous and scaly. The ear was so swollen that I thought of erysipelas, but she had no fever. She has grown worse; her face and arms in particular are erythematous, swollen and scaly. There are places where the superficial epidermis seems lost and serum exudes. The urine had a very faint trace of albumin at the last examination. She is in bed on a bland diet with a soothing lotion for the skin. Is this a dermatitis from the neoarsphenamine or is it something else? If it is from the neoarsphenamine, what would be the treatment?

M.D., Ohio.

Answer.—This case illustrates the need of a careful diagnosis before treatment is begun. The enlargement of the sternal end of the clavicle was probably a gumma; but the definite irregular macules here and there were probably something else and may have had some relation with the sensitiveness to neoarsphenamine. The eruption as described is a typical exfoliative dermatitis, undoubtedly from the treatment. The measures already taken are good. As the oozing ceases and the whole eruption becomes scaly, an ointment will probably be more beneficial than the lotion. Equal parts of wool fat and ointment of rose water, in which is incorporated 10 per cent boric acid, should be comforting. Sodium thiosulphate, beginning with 0.3 Gm. and increasing up to 1 Gm., should be given daily intravenously if well borne. The U. S. P. drug should be used. After the full dose has been reached, it may be given every other day. Once or several times a day the patient should be given a "colloid" bath, made by dissolving a cupful of baking soda in a tubful of water at 100 F., then adding a gauze bag in which three cupfuls of oatmeal has been boiled, stirring it about in the bath and squeezing the bag to get the fine emollient portion into the water. The water should be about 98 F. when the patient enters, and the tub should be protected as much as possible from drafts by blankets over it. The length and frequency of the bath must be regulated by its effect. At the end of the bath, the patient should be dried gently by dabbing with the towel, and the ointment should be applied at once.

Roentgen treatment, one-fourth erythema dose of soft, unfiltered rays to each part once a week, treating only a part of the body at one sitting, is beneficial. The erythrocyte count should be watched during this time. If it falls much below normal, the roentgen treatments should be stopped.

VAGINITIS IN CHILD

To the Editor:—A girl, aged 4 years, has had vaginitis of five months' duration. When I first saw her, January 15, six weeks after the onset, there was a rather abundant purulent discharge, some redness of the mucous membrane, and slight excoriation of the labia and inner surface of the thighs, in addition to frequency and burning on urination. The urinary symptoms disappeared within a week following medication. January 15 she was started on potassium permanganate irrigation, 1: 4,000, for twenty minutes twice a day. In a series of smears from the vagina, cervix and urethra, examined at the state laboratory at Houghton, Mich., gonococci were never found but pus cells have been found, in fewer numbers recently than when first taken two and one-half months ago. The child is well nourished. Her personal cleanliness is excellent. She has had no symptoms referable to the genito-urinary tract for the last two months except occasionally a drop of pus from the vagina when a douche is being given. What do you advise in treatment? Would you advise local applications of silver nitrate 10 per cent or mild silver protein 20 per cent? Are recurrences unusual? The local condition is greatly improved but her family is discouraged with the amount of progress, believing that a complete cure should have been accomplished before this. I had been of the opinion that it is often a matter of months before such a condition is markedly improved, as checked by successive smears negative for gonococci and pus cells. Please omit name.

M.D., Michigan.

Answer.—The management depends on the location of the inflammatory lesion. This is best determined by vaginoscopic examination by means of the illuminated vaginoscope or female urethroscope. Punctate lesions are sometimes discovered on the cervix or upper part of the vagina, which may be treated topically with weak solutions of silver nitrate. Skene's tubules at the base of the urethra should also be closely examined, as they may harbor the organism. If pus is expressed from Skene's tubules, irrigation with 5 per cent aqueous mercurochrome-220 soluble by means of a soft-nosed fine cannula is usually successful. Recurrences are not uncommon in vaginitis due to latent infection in the glandular structures. The fact that the smears have been negative for gonococci does not prove definitely that the infection is nonvenereal. There is a nongonorrheal variety, however, which clears up as a rule much sooner than the gonorrheal and is less likely to recur. Rarely, Trichomonas vaginalis is found in the vagina of young girls, producing the symptoms described. These are easily detected by examining the secretion in fresh hanging drop with an equal amount of physiologic solution of sodium chloride. The flagellates are then seen actively moving in the field.

The success of the therapy depends on the original cause of the infection. The vaginal instillation of 1 per cent mercurochrome ointment daily has proved successful in clearing up gonorrheal infection in about ten to twelve weeks' treatment, and the nongonorrheal infection has cleared up in an average of five weeks. It is not uncommon, however, for the course to be prolonged many months or even a year when treatment is given by means of douches. Further details may be found in an article on cervicovaginitis by Irving F. Stein, M. L. Leventhal and Harry Sered in the *American Journal of Diseases of Children* **37**:1203 (June) 1929.

BULLAE ON FEET OF DIABETIC PATIENT

To the Editor:—A man, aged 60, with diabetes mellitus, now under control, has developed a serious bulla on the dorsum of his left foot. This has healed after four weeks of rest in bed, elevation of the limb, and the use of a light cradle. The area surrounding the bulla becomes bluish when he is on his feet. The left anterior tibial artery is palpable, though not so plainly palpable as on the right side. The systolic blood pressure is 180; diastolic, 80. The urine is negative for sugar and albumin. The blood sugar is 120 mg. per hundred cubic centimetetrs. What is the prognosis for recurrence? Kindly omit name.

M.D., Wisconsin.

Answer.—The formation of such a bulla is frequently indicative of the onset of localized gangrene, although some patients will have several recurrences without a true gangrenous condition developing. From a therapeutic point of view, it is suggested that in addition to the elevation of the limb the Buerger exercises or the contrasting hot and cold local baths be instituted.

DANGER OF EXPOSURE TO X-RAYS

To the Editor:—A technician is taking roentgenograms of the extremities, the teeth and the gastro-intestinal tract. The entire duration of exposure averages five or six minutes per month. In addition to it, x-ray treatments of superficial skin lesions are given; 0.5 or 1 mm. of aluminum is used as a filter; 85 kilovolt peak is used. The entire duration of all the treatments per month averages an hour. The tube is always placed in such a manner that the rays go in a vertical direction, straight downward. During the treatments the technician is in the adjoining room; the walls are not insulated with lead. The room is well ventilated. Do you consider the secondary radiation as strong enough to cause sterility in the young girl or affect her health in any manner? Kindly omit name.

M.D., Illinois.

Answer.—There is no reason to expect any untoward action on the technician from the circumstances described. Epilation or dermatitis would be likely to occur before there would be any effect on the ovary, on the assumption, of course, that the rays are vertical and that the x-ray tube is either enclosed in a lead-glass protection bowl with the apertures directed away from the position of the technician or that the tube is of a self-protecting type. Under all circumstances it is advisable that protection for technicians be provided.

SENSITIZATION TO ARSPHENAMINE

To the Editor:—I have a syphilitic patient, aged 23 years, who had a chancre about three months ago. His Wassermann reaction was 4+. He received three intravenous injections of 0.3 Gm. of neoarsphenamine, one of 0.45 Gm. and nine of 0.6 Gm. After the third injection of 0.6 Gm. of neoarsphenamine, I gave 1 cc. solution of thiobismol, a bismuth preparation, intramuscularly for six doses, on the fifth day following each 0.6 Gm. neoarsphenamine injection. At the end of this series, the last 0.6 Gm. neoarsphenamine injection, the patient had an immediate nitritoid reaction, as evidenced by sneezing, pruritus, fulness in the head and nausea. This was relieved by 5 minims (0.3 cc.) of solution of epinephrine hydrochloride subcutaneously and two three-eighth grain (0.024 Gm.) capsules of ephedrine sulphate. The Wassermann reaction was negative at this time. Three weeks later the same reaction occurred with 0.3 Gm. of neoarsphenamine, which was relieved with epinephine hydrochloride and ephedrine sulphate. Kindly inform me how long a rest period a patient of this type should be given. Would you advise the intramuscular injections of bismuth now; if so, how many? There apparently was no improper technic in the preparation of patient, solution or administration. Kindly omit name.

M.D., New Jersey.

Answer.—The patient has in some way become sensitized to neoarsphenamine. The treatment with bismuth or mercury compounds should be continued. After a month or so, other forms of arsphenamine may be tried with great caution, arsphenamine U. S. P. or sulpharsphenamine bismuth. If these can be given, treatment with them and with bismuth or mercury compounds should be continued for at least two more full courses before a rest period longer than two weeks is given. The bismuth treatment so far has been mild. A more vigorous treatment lasting at least eight weeks and not over twelve weeks can be called a course. The chief consideration, naturally, is the continued good health of the patient, and any course of treatment has that as the aim.

LEUKOPLAKIA

To the Editor:—I have a patient about 50 years of age with leukoplakia of the tongue. I removed several large plaques, one of which was undergoing malignant degeneration. These were removed by electrocoagulation and the bases were treated with radium. The submental, sublingual and cervical glands were treated with high voltage x-rays to prevent metastasis. The areas of the large plaques are now smooth and contain no induration. There is, however, a thin uniform white coating resembling a thin leukoplakia covering the entire dorsum and sides of the tongue, excepting the few areas where the large plaques have been removed, which has been present for some years. How can this be removed? Is there any known cause to which this condition can be attributed?

C. W. Koehler, M.D., Cincinnati.

Answer.—Chronic irritation is the accepted etiologic factor in the causation of leukoplakia. Leukoplakia of the buccal mucosa is intimately associated with carious teeth, tobacco and syphilis. Further extension of existing leukoplakia in the mouth may be prevented by removing all sources of irritation. Carious teeth must be extracted, sharp edges smoothed, and incorrectly constructed dentures corrected. Smoking must be stopped and chewing tobacco prohibited. When there is evidence of syphilis, antisyphilitic treatment should be administered.

A localized area of leukoplakia may be removed by excision. Extensive areas of leukoplakia present a difficult therapeutic problem. Removal of all possible sources of irritation in most instances arrests the process and frequently improves the local condition.

X-RAY BURNS OF LIP

To the Editor:—I have a patient with x-ray burns of the lip and would appreciate literature giving the diagnosis and prognosis or general information. The burn is not very large, about the size of a pea, and barely through the skin. A machine was used with 60 cycles, 30 amperes and 5 kilowatts. Two sets of pictures were taken about two weeks apart. Please send this information as soon as possible.

E. R. Doering, D.D.S., Parkston, S. D.

Answer.—Unless a patient has had previous roentgen treatment it is unusual for a third degree x-ray ulcer to develop two weeks after one x-ray exposure. It is likewise unusual for a second degree ulcer to be so small as the one described. This naturally raises the question of diagnosis. For the protection of the operator, as well as the patient, it would be wise to have a consultation with either a dermatologist or a roentgenologist, to determine the exact nature of the disease, and the treatment would of necessity depend on the nature of the condition.

In the case of second degree radiodermatitis, soothing lotions, such as the well known calamine lotion, or a wet dressing with physiologic solution of sodium chloride should be used. In the case of third degree ulcerations, excision is the proper remedy once the condition has become localized.

A full description and bibliography may be found in MacKee's book: X-Rays and Radium Treatment of Diseases of the Skin.

MIGRAINE WITH OCULAR PRODROMALS

To the Editor:—At indefinite intervals (possibly on two or three successive days or, more frequently, at intervals of from three to six weeks) a patient has an attack beginning with slight dimness of vision, which gradually becomes more pronounced and in ten or fifteen minutes it is accompanied by scintillating zigzag lines (at the right upper side of the visual field), which continue for from fifteen to twenty minutes and then disappear, leaving the vision normal and the patient with a dull headache, which continues for about twenty-four hours. There is no vertigo, nausea or vomiting. No cause has been determined. Would you consider this a form of transient hemianopia or possibly an early sign of some organic disease? Can you suggest any treatment?

E. V. Valz, M.D., Parris Island, S. C.

Answer.—In all probability the patient is suffering from a form of migraine with ocular prodromals. The tempory dimness of vision accompanied by scintillating scotomas, either with or without contraction of the visual fields, followed by a headache of many hours' duration is quite characteristic of this condition. Local therapy or correction of errors of refraction has been entirely without avail. Some cases have responded to the systemic use of cannabis, others to phenobarbital, while in still others intestinal lavage has proved of value.

INJURY TO SPINE BY FALL

To the Editor:—In jumping from a ladder, Aug. 12, 1931, a man landed on a pipe, which rolled under his feet and caused him to fall more or less in a sitting position. Since the injury he has been unable to work on account of pain in the lumbar region. The physical examination is essentially negative. The roentgen examination is negative. The consultation diagnosis is traumatic myofascitis and the statement is made that this type of trouble is stubborn and resists all types of treatments sometimes for many months. I would appreciate any information that you may give me on the diagnosis and prognosis of this case.

W. Ellwood Tew, M.D., Bessemer, Mich.

Answer.—The diagnosis and opinion of the consultant who sees the patient is much more reliable than might be expressed by any reviewer of the question. The condition described is evidently analogous to rupture of the supraspinatus, achilles, plantaris or biceps tendons. It is impossible to make a positive diagnosis from the data supplied. The prognosis, therefore, must be guarded. The treatment may be outlined to include any or all of the following factors: rest, immobilization, support for a short period, and physical therapy consisting of radiant heat, gentle massage and diathermy cautiously applied.

AGRANULOCYTOSIS

To the Editor:—In the literature, frequent reference is made to the disease agranulocytosis. The terms leukocytosis and lymphocytosis indicate an increase in these types of cells. In the disease first mentioned there is a decrease in granulocytes, as indicated by the prefix a. It seems to me that the word is improper, with the suffix osis indicating an increase and the prefix a indicating an absence. I should like to know whether this term is correct to use. Please omit name.

M.D., California.

Answer.—The term agranulocytosis is the one most widely used to describe the condition which is also called malignant neutropenia, idiopathic neutropenia, agranulocytic angina and granulocytopenia.

The a is not a prefix. The word agranulocyte was the term originally chosen for neutrophils without granulations appearing in leukemia. Thus, agranulocytosis means an increase in these atypical neutrophils. Actually the condition is a decrease in cells of the myeloid series and sometimes an increase in lymphocytes, so that idiopathic neutropenia is probably a better name for the condition.

The term agranulocytosis and the term agranulocytic angina have become so firmly established in the literature that it is doubtful whether they can be supplanted.

POSSIBLE CAMPHOR POISONING

To the Editor:—A woman who has taken camphor dissolved in water in teaspoonful doses at frequent intervals for many years presents the blood picture of pernicious anemia, has peripheral neuritis with bilateral wrist drop and toe drop, and has considerable atrophy of the muscles and subcutaneous tissue. Considerable gastric discomfort is complained of, and pain in extremities. The onset began in December with pain in the extremities. December 10, the blood picture was normal. There is no history of metallic poisoning, jamaica ginger addiction or alcoholism. The camphor preparation she has made by dissolving the black or crude camphor in boiling water and storing for use. She is somewhat indefinite about the amounts taken, but has taken more since December, when she first fell ill. Is the camphor responsible for this condition or can it be attributed to impurities in the camphor, perhaps a benzene product which is used in the preparation of camphor commercially. Please omit name.

M.D., Massachusetts.

Answer.—The employment of camphor in the manner indicated is certainly most unusual, and probably for this reason the clinical picture described has not been noted in connection with chronic camphor poisoning. There is a possibility that the camphor might be responsible for the condition observed.

COLORIMETER FOR CLINICAL USE

To the Editor:—I should like to have some information in regard to the efficiency of the Kuttner-Leitz Micro-Colorimetetr, sold by E. Leitz, Inc., New York.

Rafael Cowley, M.D., Havana, Cuba.

Answer.—The Kuttner-Leitz Micro-Colorimeter is a satisfactory and convenient instrument for clinical use. A number of the methods have been revised since the colorimeter was first made but this has not seriously interfered with the results for clinical purposes. It is advisable to determine normal values among patients with this instrument, as the figures are apt to be a little higher than those commonly quoted. In the use of a microcolorimetric method, technic is an important consideration and the relative accuracy will depend to a large extent on the efficiency of one employing the instrument.

NOSEBLEED

To the Editor:—I have charge of an institution in which a few of the boys have nosebleed. Is there any medicine that can be given to control this condition? Squibb puts out a thromboplastin for hypodermic use. Flint, Eaton & Co. put out some kind of a preparation in fluid form to be given in tablespoonful doses. Are these preparations of value?

J. B. MAXWELL, M.D., Butlerville, Ind.

ANSWER.—There is no satisfactory evidence as to the hemostatic value of the various "thromboplastins" when they are given by mouth. Their intravenous administration is dangerous. The Council on Pharmacy and Chemistry accepts such preparations for local use only. Calcium salts, such as the lactate, have been advocated; and a trial of these may be indicated for repeated hemorrhages. Local treatment, such as pinching the nostrils so as to press the alae tight against the septum, will stop the bleeding in a large percentage of cases. Usually the bleeding spot can be seen on the septum and the bleeding stopped by cauterizing it with silver nitrate or by applying to it powdered potassium permanganate.

ORTHODONTIA

To the Editor:—At what age is it best to have a child's teeth straightened? My child at present is 9 years old and a few teeth are not straight. Please omit name.

M.D., Indiana.

ANSWER.—As a general rule, it is recommended that the correction of irregularities of the teeth be undertaken before the child is 10 years of age. In some cases much can be accomplished before the first permanent molars erupt (about the sixth year). These teeth are the key teeth, so far as irregularities are concerned. Normally these teeth should meet in such a way that the upper first molar is slightly farther back and stands farther out toward the cheek than the lower first molar; that is, the upper molar should overlap the lower to the back and to the outside. If these four teeth (one above and one below on either side) are in proper positions, they serve to maintain the relation of the upper to the lower jaw while the baby teeth are shed and the other permanent teeth erupt, and the rest of the teeth are likely to come in in their proper positions. If these molars are not in proper relation, irregularities of the other teeth are likely to occur.

If the temporary molar teeth happen to be in wrong positions, this often disturbs the position of the first permanent molars. Therefore, attention to the baby molars a few months before the permanent molars erupt is often highly important.

In cases in which it is necessary to use regulating appliances, it is probably best, as a general rule, to begin about the eighth year. The younger the child, the faster the corrections can be made, as the necessary changes in the bone about the teeth occur more rapidly.

TESTS OF PATERNITY

To the Editor:—I have somewhere seen described a test known as the Mayoral and Jiminez paternity test. In this test an emulsion in isotonic saline solution of the father's blood is injected subcutaneously into the pregnant woman's arm. An erythematous and slightly painful reaction occurs within six hours. A similar emulsion from any other man gives a negative result. Is this reaction at present accepted as definite proof of paternity in medicolegal cases?

NATHAN H. MOSS, M.D., Detroit.

ANSWER.—No, the reaction mentioned has no medicolegal standing.

TREATMENT OF SOFT CORNS

To the Editor:—In Queries and Minor Notes (THE JOURNAL, April 16) I note an answer relating to the treatment of soft corn. I should like to add that nearly all of these so-called soft corns are really plantar warts. When these lesions occur in children they may often be eradicated by applying a paste of 50 per cent salicylic acid directly over the lesion and holding it in place for a few days with a small corn pad covered by adhesive plaster. This allows a deep removal of the calloused tissue and often destroys the wart. It may be necessary to repeat this treatment immediately following the first treatment. In intractable cases, and in adults, it is necessary to follow with a destructive dose of x-rays or radium to the closely shielded lesion. Because of the location of the lesion, it is usually more convenient to employ radium than x-rays. Many of these lesions will disappear following the application to them of a crystal of monochloracetic acid the size of a small split pea. This dissolves into the corneous wart and seems to have a selective action. Trichloracetic acid will not do. The area is quite sore for a few days following this procedure. Destruction by electrodesiccation and the like is apt to cause many days of disability and is usually not desired. These lesions are autoinoculable and contagious and often appear on contiguous surfaces of adjacent toes. In very stubborn cases surgery may be considered, but, because of autoinoculation, recurrences are common. The essential in the treatment of a so-called soft corn is the consideration that pathologically it is a verrucous lesion of the plantar wart type.

HERBERT H. BAUCKUS, M.D., Buffalo.

Book Notices

Female Sex Hormonology: A Review. By William P. Graves, A.B., M D , F.A.C.S , Professor of Gynecology at Harvard Medical School. Cloth. Price, $3.50. Pp. 131, with 9 illustrations. Philadelphia: W. B. Saunders Company, 1931.

Great confusion exists in the minds of most physicians, owing to the multiplicity of terms used in various publications concerning the female sex hormone. A great deal of experimental work has been done, but no uniformity has been employed in terminology by the experimenters. The glossary that the author has appended to this work alone justifies its publication. In addition, Graves, who has been an interested and active clinical investigator of preparations of the female sex hormone, has simplified the present status of this portion of endocrinology in an acceptable and easily readable form. A complete story in brief of the physiology of the female reproductive system is described in the light of our modern conception, based on a vast amount of scientific work done in the past few years. All students of medicine would profit by carefully reading this concise review of the subject, which, the author justly points out in his introduction, is not at the close but at the beginning of its great ultimate development. A complete practical bibliography and an adequate index are appended.

Selected Writings of John Hughlings Jackson. Volume II: Evolution and Dissolution of the Nervous System, Speech, Various Papers, Addresses and Lectures. Edited for the Guarantors of "Brain" by James Taylor, M.D., F.R.C.P., with the Advice and Assistance of Gordon Holmes, M.D., F.R.C.P., and F. M. R. Walshe, M.D., F.R.C.P. Cloth. Price, 25 shillings. Pp. 510. London: Hodder & Stoughton, Ltd., 1932.

A review of volume I appeared in THE JOURNAL, Dec. 26, 1931, page 1984. The present, and last, volume has three divisions: section I, 118 pages, containing addresses and papers relating principally to what Jackson called "evolution and dissolution" of the nervous system, principally dissolution; section II, 91 pages, articles relating to disorders of speech; section III, 269 pages, various papers, addresses and lectures. A full chronological list of Dr. Jackson's publications (from 1861 to 1909) and a good index close the volume. What was said of volume I may equally be said of this one: it "contains such a mass of information that detailed review is out of the question but no physician can read it without learning a multitude of things, besides enjoying a scientific banquet of neurologic knowledge."

The articles on dissolution of the nervous system present a broad base for a logical conception of diseases of the brain and cord. The author first succinctly defines evolution and then shows how disease is a corresponding dissolution, though "scarcely ever, if ever, do we meet with a case of dissolution which we can suppose to be the exact opposite of evolution." He here presents his oft-repeated thesis: "I submit that disease only produces negative mental symptoms answering to the dissolution, and that all elaborate positive mental symptoms (illusions, hallucinations, delusions and extravagant conduct) are the outcome of activity of nervous elements untouched by any pathological process; that they arise during activity on the lower level of evolution remaining."

It must be a comprehensive philosophy of scientific pathology that enables one rationally to compare insanity, hemiplegia and progressive muscular atrophy. This Jackson does with admirable lucidity. Not only psychiatrists and neurologists but also, perhaps especially, psychoanalysts will find these chapters a mine of rare richness. Dr. Jackson's exposition of the relations of consciousness, voluntary movement, convulsion and paralysis is an extraordinary example of fecund philosophical thinking—with practical application.

Of section II, naturally a good bit is chiefly of historical value; but the combination of skilful clinical neurology, practical psychology, meticulous observation and philosophic generalization at the command of a man writing sixty-six years ago is truly amazing. A few disjointed quotations may be indicative. "To locate the damage which destroys speech and to locate speech are two different things." "Speaking is not merely the utterance of words." "Speaking is propositionizing." "We must not classify on a mixed method of anatomy, physiology and psychology any more than we should classify plants on a mixed natural and empirical method, as exogens, kitchen herbs, graminaceae and shrubs." "Can an aphasic make a will? cannot be answered any more than the question 'Will a piece of string reach across this room?'" "We must not say that the 'memory of words' is a *function* of any part of the nervous system." "There is no 'power' or 'faculty' of speech apart from words revived or revivable in propositions. . . ." "We must study subjects so complex as this empirically before we study them scientifically." "We must be very careful how we use the word 'cause' with regard to disease and symptoms. We must never speak of distructive lesions causing positive symptoms." In explaining the difference between "external" and "internal" speech, Dr. Jackson uses the rather startling but apt illustration of the state of a deaf mute (who talks with his fingers), losing both arms by amputation.

Section III shows Jackson's versatility. Lack of space precludes going into details. The address on the psychology of joking in a pleasing way exhibits the author's mental agility. While abounding in wit and humor, it shows the same keen insight, the same striking comparisons, the same inductive reasoning characteristic of his apparently more serious papers.

The oration on ophthalmology in its relation to general medicine (1877) would be a credit to any living physician. Indeed, no one comes to mind who could even now do the job so well. The paper on the diagnosis and treatment of diseases of the brain contains an amazing wealth of erudition, of stimulating suggestions and profound reasoning. It was delivered forty-four years ago, and no neurologist of today can read it without enriching his mental equipment.

Over against thousands who can acquire great stores of knowledge, rare scores learn to think. John Hughlings Jackson was a prince in this smaller company. He was more: a seer, a prophet, a voice crying in the wilderness; a pioneer, scientific reformer, an earnest, totally unselfish preacher; a persistent seeker for and broadcaster of truth. But in all justice it must be added that Jackson did not write for him who wishes to run as he reads nor for such as—to paraphrase a late beloved colleague—start their eyes to reading and then go off and leave them.

That every reference medical library will have these volumes is a foregone conclusion. That all thoughtful neurologists and psychiatrists will possess and read them is devoutly to be hoped. The medical historian cannot ignore them.

How's Your Blood Pressure? By Clarence L. Andrews, M.D., Attending Physician and Medical Chief at the Atlantic City Hospital. Cloth. Price, $2.50. Pp. 225. New York: Macmillan Company, 1931.

This is an outline of the more common and salient features of blood pressure, normal and abnormal, written in a style that should appeal to the lay reader. The book covers the relation of food, work, worry, heredity, sex and exercise to blood pressure. The chapter on the physiology of the circulation is a bit too complicated for the average person to grasp, and the chapter on the methods of estimating blood pressure might well have been omitted.

Neoplastogenesi: Di una soluzione veramente integrale del secolare problema riguardante l'origine dei tumori. Per Dott. Enrico Gilardoni. Paper. Price, 5 lire. Pp. 91. Rome: Edizioni Sapientia, 1930.

Prof. P. N. Gregoraci of the University of Naples announced in 1925 that all new growths, whether in man, lower animals or plants, owed their genesis to symbiosis between certain micro-organisms and the cells of the host. In man, according to the theory, the spirochete of syphilis accounts for the origin of 75 per cent of cancers, while the tubercle bacillus, the malaria parasite and the gonococcus are the exciting agents for the remainder. The author of the present treatise, inspired by the originator of the doctrine, as well as, according to a foreword, by the death of his mother from a malignant tumor, lays before the world his exposition of the thesis embellished with emotional excursions as uncritical as they are warm.

The Practical Medicine Series Comprising Eight Volumes on the Year's Progress in Medicine and Surgery: General Medicine. Edited by George H. Weaver, M.D.; Lawrason Brown, M.D.; George R. Minot, M.D., S.D.; William B. Castle, M.D.; William D Stroud, M D., and Ralph C. Brown, M.D. Series 1931. Cloth. Price, $3. Pp. 814, with 24 illustrations. Chicago: Year Book Publishers, Inc., 1931.

The Practical Medicine Series Comprising Eight Volumes on the Year's Progress in Medicine and Surgery: Dermatology and Syphilis. Edited by Fred Wise, M.D., Professor of Dermatology and Syphilology, New York Post-Graduate Medical School and Hospital of Columbia University, and Marion B. Sulzberger, M.D., Associate in Dermatology and Syphilology, New York Post-Graduate Medical School and Hospital of Columbia University. Urology. Edited by John H. Cunningham, M.D., Associate in Genito-Urinary Surgery, Harvard University Post-Graduate School of Medicine. Series 1931. Cloth. Price, $2.25. Pp. 472, with illustrations. Chicago: Year Book Publishers, Inc., 1932.

The Practical Medicine Series Comprising Eight Volumes on the Year's Progress in Medicine and Surgery: General Therapeutics. Edited by Bernard Fantus, M.S., M.D., Professor of Therapeutics, University of Illinois College of Medicine, and Louis B. Kartoon, B.S., M.D., Instructor of Medicine, University of Illinois College of Medicine. Series 1931. Cloth. Price, $2.25. Pp. 467, with 53 illustrations. Chicago: Year Book Publishers, Inc., 1932.

The Practical Medicine Series Comprising Eight Volumes on the Year's Progress in Medicine and Surgery: Obstetrics. Edited by Joseph B. DeLee, A.M., M.D., Professor of Obstetrics, University of Chicago Medical School. Gynecology. Edited by J. P. Greenhill, B.S., M.D., F.A.C.S., Attending Gynecologist, Cook County Hospital. Series 1931. Cloth. Price, $2.50. Pp. 665, with 44 illustrations. Chicago: Year Book Publishers, Inc., 1932.

The Practical Medicine Series Comprising Eight Volumes on the Year's Progress in Medicine and Surgery: Pediatrics. Edited by Isaac A. Abt, M.D., Professor of Pediatrics, Northwestern University Medical School with the collaboration of Arthur F. Abt, M.D., Assistant in Pediatrics, Northwestern University Medical School. Series 1931. Cloth. Price, $2.25. Pp. 569, with 37 illustrations. Chicago: Year Book Publishers, Inc., 1932.

The Practical Medicine Series Comprising Eight Volumes on the Year's Progress in Medicine and Surgery: The Eye. Edited by E. V. L. Brown, M.D., Professor of Ophthalmology, University of Chicago, and Louis Bothman, M.D., Associate Professor of Ophthalmology, University of Chicago. The Ear, Nose and Throat. Edited by George E. Shambaugh, M.D., Professor of Otology, Rhinology and Laryngology, Rush Medical College of the University of Chicago, and Elmer W. Hagens, M.D., Instructor in Otology, Rhinology and Laryngology, Rush Medical College of the University of Chicago. Series 1931. Cloth. Price, $2.50. Pp. 629, with 20 illustrations. Chicago: Year Book Publishers, Inc., 1932.

The Practical Medicine Series Comprising Eight Volumes on the Year's Progress in Medicine and Surgery: General Surgery. Edited by Evarts A. Graham, A.B., M.D., Professor of Surgery, Washington University School of Medicine. Series 1931. Cloth. Price, $3. Pp. 804, with illustrations. Chicago: Year Book Publishers, Inc., 1932.

The Practical Medicine Series Comprising Eight Volumes on the Year's Progress in Medicine and Surgery: Neurology. Edited by Peter Bassoe, M.D., Clinical Professor of Neurology, Rush Medical College of the University of Chicago. Psychiatry. Edited by Franklin G. Ebaugh, A.B., M.D., Professor of Psychiatry, University of Colorado Medical School. Series 1931. Cloth. Price, $2.25. Pp. 471, with 28 illustrations. Chicago: Year Book Publishers, Inc., 1932.

This series, printed over many years, shows a new trend for 1931 and 1932. Instead of being a haphazard collection of abstracts, it now presents the literature in various fields with critical comments by the editors on the abstracts that they consider worthy of publication.

In the field of medicine, the six editors have taken this responsibility seriously, and their comments are invariably enlightening. Special sections on undulant fever, tularemia and psittacosis indicate the timeliness of the material. It is felt that the use of vaccines in whooping cough is still an open question, that convalescent serum for the prevention of measles is an established measure, that diphtheria toxoid is gradually replacing toxin-antitoxin for diphtheria, and that rabies may be eliminated by strict enforcement of the muzzling laws. The reports on the use of stramonium in encephalitis are encouraging. Family physicians are urged to assume their responsibility in vaccination against smallpox, since there are still 50,000 cases of smallpox annually in this country. The discussion of colds by Lawrason Brown reveals the failure thus far to control this most common of diseases. The mucin treatment of gastric ulcer and duodenal ulcer is given consideration, and the editor does not feel that it presents any considerable improvement over the Sippy technic. There is beginning to be a reasonable classification of blood dyscrasias with the development of new information from various clinics.

In the book on surgery, now edited by Evarts A. Graham, special attention is paid to thrombosis and embolism, the maggot treatment of osteomyelitis, the rate of healing of wounds, spinal anesthesia and phrenicectomy. This volume is marked not only by numerous thoughtful editorial comments but also by the excellence of the abstracts.

The volume on therapeutics, by Fantus and Kartoon, summarizes the literature made available during the year and is full of practical hints for everyday use in the practice of medicine. The classification of the therapeutic technics is unusual and is concerned with physiologic actions rather than with materia medica.

The volume on neurology and psychiatry brings its subject quite down to date and reveals a conservative attitude toward psychoanalysis. Thus, in criticizing an article on psychoanalysis and eye disturbances, Dr. Ebaugh says: "Psychoanalysis is open to the criticism of not being objective and scientific on the basis of articles of this type which are unrelated to case material." No doubt the psychoanalysts have introduced into medicine more imagination and theory than has been brought into the field in any other branch of medical study.

The volumes on the various specialties are limited largely to abstracts of new contributions to the field concerned and thus supply new material rather than complete reviews. Apparently evidence is beginning to be developed to support Noguchi's conception of the cause of trachoma. There continues to be considerable argument as to just when a dead tooth should or should not be removed.

The volume on pediatrics opens with an excellent outline of the social position of pediatrics by Dr. Isaac A. Abt. It includes considerations of progress in every field of medicine, since pediatrics must be, after all, a complete consideration of medicine as applied to the child.

The volume on obstetrics continues to present the views of DeLee and his school in the usual satisfactory manner.

The volume on dermatology and syphilis appears with two new editors, who point out that they have chosen their material largely with the general practitioner in mind. The abstracts are extensive, in fact so extensive that they may indicate the lack of experience of the authors in selecting exclusively significant material.

Opuscula selecta Neerlandicorum de arte medica. Fasciculus decimus quem curatores miscellaneorum quae vocantur Nederlandsch Tijdschrift voor Geneeskunde collegerunt et ediderunt Amstelodami Sumptibus Societatis. [An Account of the Diseases, Natural History and Medicines of the East Indies. Translated from the Latin of James Bontius]. *Cloth. Pp. 459,* with illustrations. Amsterdam: Sumptibus Societatis, 1931.

This volume in the series of reprints of Dutch medical works, published by the *Nederlandsch Tijdschrift voor Geneeskunde,* contains the writings of Bontius on tropical medicine and natural history. M. A. Van Andel writes an interesting introduction about Bontius and his career, with bibliographic and other details. Jacobus or James Bontius, 1592-1631, became doctor of medicine in 1614 and practiced in Leyden ("plague-doctor" in 1624-1625) until he was appointed doctor, apothecary and surgical inspector in the Dutch East Indies in 1626. He arrived in Batavia in September, 1627, and died, Nov. 30, 1631. During this brief but strenuous period he made for the first time "a more or less methodic survey of the principal diseases to be found in the Indian Archipelagio" and wrote in Latin an account of his medical studies as well as of botanic and zoological observations. This work is now reproduced in Latin text with English translation. In 1769 the first four books were published in London under the title "An Account of the Diseases, Natural-History and Medicines of the East Indies. Translated from the Latin of James Bontius, Physician to the Dutch Settlement at Batavia." This translation, which is evidence of the importance attached to the work at that time, is used in the volume under consideration; books 5 and 6, which deal with animals, plants and spices, have been translated by A. Quiredo. The third and fourth books constitute a pioneer work on tropical medicine. The first chapter of the third book gives perhaps the earliest detailed description of beriberi. Dysentery—from which Bontius himself was a sufferer and which he regarded as infectious in nature—consumption, cholera, empyema, jaundice, abscess of the liver are some of the other topics considered. In all cases, directions for treatment are given. In connection with empyema and abscess of the liver, precise surgical treatment is described. Frambesia is described clearly and as resembling the "venereal disease" but differing in being produced "without any venereal embrace." Book 4 is entitled "some select observations taken from the dissection of dead bodies, and tending to throw light on the diseases above [book 3] treated of." Here are described concisely postmortem observations on meningitis, empyema, fracture of the skull, "a chronic and complicated disorder," on a man "in whom the vena cava was filled with a fat and medullary substance," abscess of the liver ("on opening the body, we found nothing of the liver but the membrane surrounding it, pretty thick like a sack, in which was still a little sanious matter resembling the water wherein flesh had been washed, and such as he had spit up for a long time"), on a person who died of a wound in the breast, etc. The last was obviously a medicolegal necropsy because of the statement "we opened the body in the presence of the magistrate." These records clearly establish Bontius as a pioneer student of morbid anatomy in the tropics. Under handicaps and difficulties of which we can form no adequate idea, Bontius in less than four years carried on a work the results of which place him among the founders of tropical medicine. He is an honor to Dutch medicine and abundantly entitled to the great distinction of the reissue in new form of his works three hundred years after his death.

The Sexual Side of Marriage. By M. J. Exner, M.D., Consultant of the Division of Educational Measures, the American Social Hygiene Association. Cloth. Price, $2.50. Pp. 252. New York: W. W. Norton & Company, Inc., 1932.

This or a similar book might well be in the possession of every couple contemplating marriage or having any sort of difficulty in making such sexual adjustments as may be essential to a well balanced and satisfying marital life. The book is well written. It is interesting without being in the least morbidly stimulating. It is easily understood without being in the least juvenile. It is scientific. The author has succeeded in doing well a task that has rarely been accomplished. The subject matter is treated in a straightforward manner and in language that leaves little to the imagination. Proper attention has been given to the emotional side of sex life and, indeed, the whole book is on a high mental, emotional and moral plane. The book is recommended to the physician who wants a book that may be trusted in the hands of his young people or of older couples with sexual maladjustments.

Arbeiten aus der dritten Abteilung des Anatomischen Institutes der Kaiserlichen Universität Kyoto. Herausgegeben von Prof. Dr. Seigo Funaoka, Vorstand der Abteilung. Serie C: Experimentelle Tuberkuloseforschung, Heft 2. Paper. Pp. 108, with illustrations. Kyoto: Anatomical Institute of Kyoto Imperial University, 1931.

The papers collected in this publication form the experimental justification for the treatment of tuberculous patients with "yatoconin." Funaoka and his school found a phosphatase and a pyrophosphatase in tuberculous tissue; they show that it is identical with the phosphatase that Robison discovered in ossifying cartilage. If a rabbit, infected with human tubercle bacilli, is given an intravenous injection of calcium diethyl phosphate, the phosphatase causes deposition of calcium phosphate in the tuberculous lesions. Injections of calcium levulose monophosphate ("yatoconin") were given to eighty patients with enlarged cervical lymph nodes. In from 8 to 12 per cent of the cases the nodes remained stationary; the remainder showed varying degrees of improvement after from fifteen to thirty injections. Good results are claimed for this treatment, even when it does not result in calcification. Funaoka expects to publish a third volume, which will give more clinical data. No opinion can be formed of the value of this treatment at the present moment.

Intracranial Tumors: Their Pathology, Symptomatology, Diagnosis and Prognosis. By Cyril B. Courville, M.D., Resident Neurologist, Los Angeles County General Hospital, Los Angeles, California. Fiske Fund Prize Essay, No. LXIV. Cloth. Price, $2.50. Pp. 158, with 33 illustrations. *Providence:* Fiske Fund Essay, 1931.

This little book, the Fiske Fund prize essay for 1929, is a rather elementary discussion of the subject. Part II, concerning the pathology of brain tumors, is a summary of recent American work, accurate in the main, although those who do not agree that neuroblasts play any part in the development of the tumor ordinarily known as spongioblastoma or glioblastoma multiforme would object to the coinage of a new term for this tumor. Part III, concerning the symptomatology of tumor of the brain, is original in that the author discusses single symptoms rather than the symptomatology of the regions of the brain, as is usually done. He is not consistent, however, for along toward the end of this part he discusses the symptomatology of the cerebellum as a whole rather than individual symptoms which may or may not arise from the lesions of the cerebellum. In part IV, concerning the diagnosis of brain tumor, the discussion of differential diagnosis is inadequate, and so also is part V, concerning the prognosis of brain tumors. Although the discussion is in the main accurate, and should be useful for students to read, the volume cannot be recommended as an adequate textbook on the subject.

Les urétrites chroniques: Diagnostic et traitement. Par R. Dossot, chef de Clinique Urologique à l'Hôpital Necker, et M. Palazzoli. Préface du Professeur Legueu. Paper. Price, 50 francs. Pp. 344, with 37 illustrations. Paris: Masson & Cie, 1932.

This book deals with one of the most troublesome chapters of urology, the care of chronic urethritis. The normal and pathologic anatomy of the urethra and its appendages is minutely gone into and on this exposition is based a rational diagnostic procedure. Particular stress is laid on the ocular inspection, and excellent colored plates illustrate the achievements of urethroscopy. The therapeutic part of this publication is complete according to the most modern standard. It is satisfactory to notice that the pertinent world literature is thoroughly considered. This monograph compares favorably with all the other publications dealing with these disorders.

A History of Smoking. By Count Corti. Translated by Paul England. Cloth. Price, $3.50. Pp. 296, with 64 illustrations. New York: Harcourt, Brace & Company, 1932.

Long before civilized man began to sacrifice at the altar of Madame Nicotine, smoke had been used by the Mayas and by various savages in their religious customs. Then Columbus discovered America, and white men had opportunity to observe Indian customs. The great Oviedo wrote, after observing smoking by the Indians, "I cannot imagine what pleasure they derive from this practice unless it be the drinking which invariably precedes the smoking." Count Corti traces the evolution of smoking from that time to the present day, calling attention particularly to the way in which it has influenced modern history. It has started social, economic and political revolutions and made many a martyr. The book by Count Corti is concerned wholly with these aspects of the subject and does not primarily concern its relationship to health. There were, of course, numerous occasions in which the battles which raged on the subject were given a health slant, but in most instances without any scientific evidence to support the arguments of the fanatics who defended either side of the subject.

Le spine bifide (Malformazioni congenite de fessure vertebrali). Per Prof. G. Jemma, libero docente e assistente di clinica ortopedica nella R. Università di Napoli. Paper. Price, 30 lire. Pp. 224, with 57 illustrations. Naples: La Pediatria, 1930.

Proceeding from definition, through historical considerations, embryology, morbid anatomy, etiopathogenesis, symptomatology, diagnosis, therapy and sequelae, the author gives a well rounded, objective presentation of the congenital malformations associated with fissures of the vertebrae. Personal observations on sixty-five patients are reported in detail, accompanied by numerous reproductions of photographs, drawings and charts. Although presenting little that is startling, the work is of value as a summary in the Italian language of the information to date. The bibliography is exhaustive.

Medicolegal

Quarantine of Patient Having Venereal Disease

(Ex parte Lewis (Mo.), 42 S. W. (2d) 21)

A St. Louis ordinance provides that every person arrested as a prostitute, keeper, inmate or frequenter of a house of ill fame be examined by a physician of the division of health. If the person examined is found to have a venereal disease in an infectious stage, he or she must be quarantined in the city hospital until no longer capable of spreading the disease. A woman arrested as an inmate of a house of prostitution was examined, found to be afflicted with syphilis and gonorrhea, and quarantined in the city hospital. She petitioned for a writ of habeas corpus to obtain her release. The parties to the suit agreed that the petitioner was lawfully quarantined if the ordinance under which she was confined was valid, and the only question before the court was therefore the validity of the ordinance.

No claim was made that the city did not have authority to legislate on the subject matter of the ordinance, but the petitioner contended that the ordinance violated the due process clauses of the federal and state constitutions. Laws and ordinances, said the Supreme Court of Missouri, prescribing regulations for the promotion of health and welfare are within the police power of the government and, if reasonable, they are not obnoxious to the due process clause of either the federal or the state constitution. This ordinance was adopted to protect and promote the health of the people. Being fairly within the police power of the city, it was held by the court to be not in violation of the constitutional provisions invoked by the petitioner.

The petitioner further contended that the ordinance was invalid because in violation of section 1 of article 6 of the constitution of Missouri, which prohibits the conferring of judicial power on an administrative officer. Apparently the petitioner contended that this ordinance undertook to confer judicial power on an administrative officer when it undertook to vest in the health officer power to determine whether or not a person arrested should be subjected to isolation and treatment. But, said the court, a power is not necessarily judicial within the meaning of the constitutional prohibition merely because the exercise of that power requires an investigation of the facts and the exercise of judgment within lines prescribed by the law which confers the power. This ordinance authorizes the health officer to determine whether or not a prisoner has a venereal disease in an infectious stage. Such authority empowers the health officer only to determine the facts on which the ordinance by its own terms operates. The determination of such facts is not the exercise of either legislative, executive or judicial power within the meaning of the constitution.

The petitioner finally contended that the ordinance violated the prohibition of the state constitution that provides that no person shall be prosecuted criminally otherwise than by indictment or information. Obviously, said the court, there is no merit in this contention, for the petitioner was not prosecuted on any charge. Isolation is neither a prosecution nor a punishment for the commission of a felony or misdemeanor.

The petition for a writ of habeas corpus was dismissed and the petitioner remanded to the custody of the superintendent of the city hospital.

Legal Test as to Charitable Character of Hospital

(William Budge Memorial Hospital v. Maughan, County Treasurer (Utah), 3 P. (2d) 258)

The William Budge Memorial Hospital claimed that its property was used exclusively for charitable purposes and by the provisions of the constitution of Utah was exempt from taxation. It procured an injunction restraining the treasurer of the county in which it was located from collecting taxes for the year 1928, which had been assessed on the real estate and buildings owned and occupied by the hospital. The county treasurer then appealed to the Supreme Court of Utah.

The test, said the Supreme Court, which determines whether a hospital is charitable or otherwise is its purpose; that is, whether or not it is maintained for gain, profit or advantage. 30 Corpus Juris 462. Here, the hospital was incorporated under the general incorporation laws of the state as a corporation organized for profit, with an authorized capital stock of $35,000, which later was increased to $50,000. The charges made for services were the standard hospital charges. No patient had ever been received against whom no charge was entered on the books of the hospital, except members of the hospital staff and their immediate families. The hospital, in 1927, had an undivided profit of $31,000 and had paid the debt incurred in constructing and equipping the main building. Considering these facts, said the court, the conclusion seems inescapable that the hospital is an enterprise for pecuniary profit and its property is not exempt from taxation.

The hospital contended, however, that it was never carried on for pecuniary profit, since no dividends were ever declared or paid. The fact, said the court, that the managing directors of the hospital deemed it advisable to permit its earnings to accumulate and to use such accumulations for additional buildings and equipment, rather than to pay them out as dividends, is not indicative of either a benevolent or a charitable purpose. It often is in line with sound business principles to withhold dividends and to convert the money into increased facilities. Certainly, every stockholder is pecuniarily benefited. His holdings in the corporation are enhanced in value. A management following such a policy might, in the course of years, after the plant had increased in value because it was not burdened by the payment of taxes, be able to dissolve the corporation to the profit of all the stockholders. Furthermore, the stockholders might at any time invoke the court against arbitrary and unreasonable conduct on the part of the board of directors in accumulating a surplus in violation of their rights to the profits of the corporation. There is not a single feature, said the court, marking the plaintiff as a charitable institution.

The judgment of the trial court enjoining the county treasurer from collecting the taxes was reversed.

Revocation of Physician's License; Ground for Revocation May Be Stated in General Terms.—"The rule obtaining in the majority of the jurisdictions which have passed on the question is that a statute providing that the license of a physician, surgeon, or dentist may be revoked by the officers or board by which such licenses are granted, is not rendered uncertain or otherwise invalid because the grounds for revocation are therein stated in general terms." 5 A. L. R., 94. "As there is no real distinction between refusing and revoking a license, the same body which may be vested with power to grant or refuse to grant a license may also be vested with the power to revoke it. . . . The board is not bound by the ordinary rules of procedure or evidence that apply in a court of law or equity. Even though there is given no right of appeal from the decision of the administrative board, the federal constitution is not violated, for the right of appeal is not essential to due process of law." 21 R. C. L. 366. A statute authorizing the board of health of the territory of Hawaii to revoke a physician's license because of "gross carelessness and manifest incapacity" is not unconstitutional. To charge a physician with "professional misconduct and gross carelessness and/or manifest incapacity as a physician" gives him due notice of the charge that he is called on to defend. There is vast difference between "unprofessional and dishonorable conduct," a phrase sometimes found in statutes of this nature, and the term "gross carelessness and manifest incapacity." The former relates to professional ethics and the personal conduct of the physician, while the latter relates to the physician's method of treatment and the degree of care exercised in the treatment of the patient, and to the physician's skill or capacity properly to diagnose and treat such patient—terms that seem to have a well defined meaning both in law and in the medical profession.—*Yoshizawa v. Hewitt (U. S. C. C. A.) 52 Fed. (2d) 411.*

Physician's Liability to Patient for Performing Criminal Abortion.—The plaintiff sued the defendant physician to recover damages for alleged injuries resulting from an abortion which he performed on her. On her testimony that the defendant performed the abortion at her request, the trial court directed a verdict in favor of the physician. The court of appeals affirmed the judgment and the plaintiff petitioned the

Supreme Court of Tennessee for a writ of certiorori. According to the great weight of authority, said the Supreme Court, the interruption of pregnancy has always been regarded as highly offensive to good morals and injurious to society. As a general rule, no court will lend its aid to one who founds his cause of action on an immoral or an illegal act. In cases of this character the application of the rule is to be determined on considerations of public policy. Where the abortion is committed with the consent of the female, she should not be permitted to invoke the aid of a court, even though she is not regarded by criminal law as an accomplice to the crime. Here the plaintiff well knew the serious consequences likely to result from such an operation and that it was both illegal and immoral. In these circumstances, certainly, she is entitled to no relief. The Supreme Court refused to disturb the judgment of the court below, in favor of the physician.—*Martin v. Morris (Tenn.), 42 S. W. (2d) 207.*

The Effects of High Protein Diets on the Course of Chronic Glomerulonephritis

Drs. William S. McCann and E. H. Keutmann, Rochester, N. Y.: Dr. McCann: Diet for patients with Bright's disease is frequently limited as to protein intake, with the exception of cases of lipoid nephrosis. Liberal protein is supposed by many to be injurious in Bright's disease. This question has given rise to much controversy. Experimental work on animals has shown that unusual amounts of protein have been given to animals in whose dietary it is unnatural. Interference with normal dietary habits of animals has been found to produce hematuria. In rabbits, high protein has been injurious only when green leaves and vegetables have been omitted from the diet.

In the early work of Newburgh and his collaborators on men, injury was produced by feeding liver (rich in nuclear substance) instead of beef muscle. Newburgh also produced hematuria by administering sodium nucleate.

Our studies of this question have covered both the intensity and the quantity factors in the pathologic process in Bright's disease. We used the method of Addis for intensity estimation and the urea clearance method of van Slyke for quantity. The subjects were four young men aged from 15 to 25 years. All were observed in the acute onset or exacerbation of hemorrhagic Bright's disease. One was in the chronic latent stage and three were in the chronic active stage. Observations extending over a year were made, during which time the diet contained about 75 Gm. of protein. The increase of the protein allowance to 200 Gm. a day for one week resulted in no ill effects. Encouraged by this result, we gave liberal protein allowances for longer periods. The process subsided in intensity throughout the period of liberal protein allowance, during the last two weeks of which liver was substituted for beef muscle as a source of protein. In the boy of 15 years, thus treated, there was no edema; the blood pressure remained normal throughout. Azotemia was increased during the higher protein periods. This is accounted for in part by the fact that it was necessary to limit fluid ingestion in order to carry out the sediment counts according to the technic of Addis. Even with this limitation, the highest value for nonprotein nitrogen observed was 45 mg. per hundred cubic centimeters and for urea 21 mg. per hundred cubic centimeters. The degree of positive nitrogen balance increased during liberal protein diets. During this period the values for urea clearance showed a tendency to increase. Similar results were noted in the other three patients; an increase in weight noted was not due to edema. Proteinuria tended to increase with an allowance of 150. Gm., but hematuria did not increase.

These observations led to the conclusion that patients in the latent or chronic active stage of hemorrhagic Bright's disease may be given diets containing from 75 to 80 Gm. of protein a day without adverse effects. In two cases an increase in proteinuria was noted when 150 Gm. a day was given, but in spite of this the renal function, as measured by the urea clearance, was not decreased. The hematuria was not increased and the renal function as measured by blood clearance improved; the blood pressure remained within normal limits and the patients improved clinically when a liberal allowance of protein was given in the diets.

Treatment of Subacute Hemorrhagic Nephritis with Streptococcus Nucleoprotein Vaccines

Drs. Clifford L. Derick and James P. O'Hare, Boston: Infection is found to be usually an important factor in the production of nephritis, particularly streptococcus infection. The studies of Longcope have emphasized this point. Hemolytic streptococci have been isolated from the throats and sinuses in these patients. The toxic filtrates of these bodies, when injected into the skin, produce a reaction similar to the Dick toxin. In our studies we submitted 670 patients to the skin test. We found the percentage of reaction greater in nephritic patients than in the average type. Our present study covers 67 patients. Eighty-three per cent of these gave reactions, of which 50 per cent were in nephritic patients. One of us (O'Hare) has called attention to the inadequacy of treatment other than rest and diet. Therefore an attempt was made to immunize some of these patients. An antitoxin made of the nucleoprotein products of streptococci was used, because it was found that patients become allergic to these products. The intravenous route was used for vaccination. The dosage had to be very carefully computed, as in patients with rheumatic fever. The attempt was made to avoid any general reaction or reaction in the urine, but the latter could not always be avoided. Sometimes albuminuria occurred. Patients were desensitized to the type of nucleoprotein to which they were most sensitive. They were followed as long as thirty-nine months and only two returned to the sensitive stage. Some patients are sensitive to a green streptococcus and some to the hemolytic streptococcus. Two patients were sensitive to both types. It was not easy to get desensitization to the green variety. Some of the patients used to have repeated colds, and of these five have had no recurrence of colds, and in others colds have been much fewer. Three cases were unsatisfactory. All these were chronic cases. This disease is definitely related to infection of the upper respiratory tract, and the streptococcus is the active agent. The patients can be definitely desensitized by the streptococcus nucleoprotein. No unfavorable results have been noted from the use of the vaccine, and the majority of patients have reacted favorably. It is therefore another useful method in our armamentarium.

DISCUSSION ON NEPHRITIS

Dr. George Baehr, New York: Much clinical observation suggests the conception of the causation of a glomerulonephritis. It is well known that the onset of an acute glomerulonephritis of scarlet fever occurs during the second week of convalescence. A number of years ago I had the opportunity of pointing out that true diffuse glomerulonephritis is rarely observed as a complication of the persistent streptococcemia of subacute bacterial endocarditis, whereas the incidence of the complication in patients with this disease, who have killed off their bacteria and become bacteria free, is even higher than after scarlet fever. Last year before this association I reported ninety-six cases of subacute bacterial endocarditis in which an anhemolytic streptococcus was persistently present in the blood stream through the long duration of the disease, and only twice was diffuse glomerulonephritis observed at necropsy, one instance being of doubtful significance. On the other hand, of fifty-nine patients who had successfully killed off their bacteria in the blood and vegetations early in the disease and who were observed in the bacteria-free stage of the disease, nineteen died of uremia as a result of a complicating diffuse glomerulonephritis, an incidence of over 30 per cent. Recently I had occasion to review fifty cases of Streptococcus hemolyticus bacteremia, and in not one instance was a diffuse glomerulonephritis found post mortem. It is therefore obvious that neither the presence of a hemolytic or a nonhemolytic streptococcus in the blood stream nor the excretion of their toxins by the kidney can be the cause of diffuse glomerulonephritis. The diffuse glomerular damage that follows streptococcal infections must be the result of phenomena concerned in recovery from infections.

D. D. VAN SLYKE, New York: I am interested in the work of Drs. McCann and Keutmann on the desirability of generous protein feeding in hemorrhagic nephritis. This fact in hemorrhagic nephritis as well as in degeneration nephritis has been confirmed by our studies at the Rockefeller Institute. We were cautious in giving generous protein diet to patients with decreased renal function, but as we have gained more experience we have found that it is desirable to use high protein to maintain the tissues in a state of good nutrition, but we kept the plasma proteins at such a level that the patients would not be edematous. At the present time I am inclined to think that there is no justification in keeping the proteins low in the diet of nephritic patients because of their nephritis. Our aim should be to keep up their nutrition and to disregard the fact that they have nephritis. We have found that the patients are in good shape until they fall into the hands of some physician. Patients often come to us with 10 or 15 per cent of renal function and in a fairly good state of health and continuing to work. They hardly realize they are ill. These patients are the ones who have had the good fortune to escape being dieted.

DR. HERMAN O. MOSENTHAL, New York: One word as to this conclusion. Such a diet has been used, and the patients ate from 50 to 75 Gm. of protein readily; but if the protein was raised beyond that point difficulty arose because patients could not consume with comfort larger amounts of protein. Consideration of the situation shows that a great error has been made in treating the kidneys solely. The kidneys are not necessarily damaged by proteins. Drs. Christian and Bartram observed that they could benefit the situation when they produced albuminuria by diuretics. As far as proteins in all types of Bright's disease are concerned, they diminish edema and prevent pneumonia. They do not change renal function; but one has to be on the lookout that in extreme cases the renal function is not overtaxed. With the exception of producing uremia, a high protein diet would be of benefit rather than harm.

DR. WARFIELD T. LONGCOPE, Baltimore: Reactions with injections have occasionally been obtained from patients. One ought to see how often these reactions occur and how serious they are. In tonsillectomy or in sinusitis there may be reactions showing red blood cells in the urine. This reaction usually subsides without doing any harm.

D. D. VAN SLYKE, New York: I do not want to give the impression that every patient has received a high protein diet. Some get 60 Gm., some 75. Unless the patient is given whatever he can take with comfort, difficulties in his general condition arise. One must take into account his digestive ability and general reaction and give him as much as he can take care of, to keep up his general nutrition, allowing for the fact that his renal function is subnormal.

DR. JAMES S. MCLESTER, Birmingham, Ala.: A more intimate knowledge of the pathology of both acute hemorrhagic nephritis and chronic degenerative Bright's disease, particularly as regards the ensuing plasma protein deficit, would indicate that in both forms of nephropathy the patient should be given diets containing liberal amounts of protein; in the former disease 100 Gm. daily, in the latter even more. Experience has shown that such an allowance facilitates recovery. In nephrosclerosis different conditions obtain, but even here there is no reason for rigid protein restriction and in order to maintain the patient's strength and vigor for the longest possible period the diet should be fairly liberal; it should provide approximately 75 to 100 Gm. of protein daily.

DR. WILLIAM S. MCCANN, Rochester, N. Y.: We do not consider very high protein diet as the optimal. I think the average patient can rarely take more than 100 Gm. with comfort. In some conditions the patient does well on a low protein diet. The effect of protein feeding on animals is worth consideration. Our studies have covered cases with the nephritic syndrome. The effect of high protein on the necessity for acid excretion must not be lost sight of. The excretion of phosphates, sulphates and acid must be considered, and the capacity of the kidney for acid base excretion must be taken into account. Our cases were in a state of subsidence from acute attacks. They were not in the early chronic active stage.

DR. CLIFFORD L. DERICK, Boston: In reply to Dr. Longcope, these patients frequently have an upset after tonsillectomy. We were able to give small doses and felt our way along. We could give about 10,000 at first. In regard to the number of treatments, we gave twelve to desensitize a patient, as far as the skin test shows desensitization.

Filtrable Forms of Bacteria and Their Significance

ARTHUR I. KENDALL, PH.D., Chicago: Almost exactly fifty years ago, Robert Koch announced the isolation and cultivation of the tubercle bacillus and demonstrated its relation to tuberculosis. Most important of all, he gave to medicine a method whereby a considerable number of bacteria could be studied in the laboratory and their relations to infectious diseases established. Improvements and refinements of method led directly to the discovery of other microbic incitants of infection, and for three decades the surge of discovery swept on. A time came, however, when there emerged from the multitude of microbic infections a formidable, heterogeneous group of diseases whose inciting agents resisted the most painstaking efforts of the laboratory. The members of this heterogeneous group failed to develop in the traditional culture mediums even when they were enriched with body fluids or bits of sterile tissue. The classic procedure of Koch had apparently reached a limit in its usefulness.

Exanthems, influenza, the common cold, certain types of arthritis, rheumatic fever and endocarditis, to mention but a few members of this group, exhibit in common three important characteristics: their inciting agents are invisible, unstainable and uncultivable in laboratory nutrient mediums thus far available. In endeavoring to discover the reason for current failure to cultivate the causative agents of these diseases, several of which are said to be filter-passing organisms, one is impressed by an important difference between the natural habitat of these bacteria in the body, and the character of the artificial medium in which their cultivation is attempted. In the body, the organisms are living in a protein environment of exquisite specificity and complexity; in the test tube, denatured protein (peptone), with or without enrichment, is offered to them. The difference between the body protein and the peptone of the laboratory mediums is really very great. Some conception of this difference may be gained when one contemplates the remarkable host specificity manifested by the virus of smallpox, for example; and some idea of the intricacy of this host-microorganism complex may be had by a consideration of the changes in virulence brought about when the human smallpox virus is modified in its virulence by passage through calves to produce vaccine virus.

If these observations are correct, it would seem reasonable to depart from the traditional peptone mediums and to offer to the refractory tissue parasites a pabulum more nearly in keeping with their natural nutritive environment; in other words, to make use of a protein-rich, peptone-poor medium in an attempt to induce them to grow outside the animal body. Such a medium (K medium), very primitive and greatly in need of refinement, has been devised. Through its use a certain amount of information has been gleaned which would lead us to hope that at least some of the problems relating to the etiology of the heterogeneous, refractory group of diseases under discussion may be more closely scrutinized. At present, the medium referred to is made from the intestines of hogs, which are first extracted with alcohol and benzene and then dried. This extracted, dried intestinal residue is immersed in Tyrode solution of proper reaction and sterilized in the autoclave. It is then ready for use. The medium falls far short of the ideal in many respects and is certainly a very poor substitute for the exquisitely specific and complex protein architecture of the tissues in which the organisms sought for are accustomed to grow; but, uncertain and crude as it may be, the hog intestine medium does seem to support the growth of organisms which have hitherto appeared to be uncultivable. To this extent it has justified itself. In it, certain bacteria, as Bacillus typhosus, have been rendered filtrable, and in the filtrable state these forms have been kept alive for several months. In this filtrable state the typhoid bacillus is invisible, unstainable, and uncultivable in ordinary mediums, and to this extent it has distinct relationship to the filtrable organisms in the body. Finally, typical typhoid bacilli, agglutinable with specific typhoid serum and having the proper morphology, staining and fermentation reactions, may be recovered from this filtrable organism. From these observations it would appear that it is logical to infer that bacteria, growing in the tissues, in the presence of protein and in the absence of peptone (unless pus formation occurs), might also be in the filtrable state invisible, unstainable and uncultivable in ordinary peptone-containing mediums. Evidence is available which indicates that such may be the case.

Observations on filter-passing and non-filter-passing bacteria in the urine seem to indicate that bacteria may exist in the body in the filter-passing state; that these bacteria in the filter-passing state are not stainable, not distinctly visible under the microscope, and not directly cultivable in ordinary nutrient laboratory mediums; that at least some of these bacteria in the filter-passing state are directly cultivable in a crude protein medium (K medium) and after development in this medium through repeated transfer they may be recovered eventually in a visible, stainable state, cultivable directly in ordinary nutrient laboratory mediums, and that these bacteria in the visible, stainable, cultivable state do not pass the pores of certain Berkefeld filters. Attention is drawn to the fact that there is a considerable group of micro-organisms growing in the tissues of the body which are not stainable, not distinctly visible under the microscope, and not directly cultivable in ordinary nutrient laboratory mediums. They are, or may be, filter-passing organisms. It is suggested from these analogies that at least certain of the micro-organisms now classified in this indefinitely defined group of "viruses" may be bacteria in the filter-passing state. The isolation and cultivation of bacteria from the urine in the filter-passing state opens up new problems of importance, both to clinical medicine and to public health. It is quite possible that typhoid, paratyphoid and other bacteria may thus escape from the body and with current laboratory methods escape detection. The relation of humoral and cellular forces of the body to bacteria in the filter-passing state is brought to the fore; nothing definite can be predicted at the present time, however.

DISCUSSION

Dr. Hans Zinsser, Boston: I have taken great interest in this problem since Dr. Kendall's first paper appeared. The subject is so fundamentally important that a correct solution must be sought by all bacteriologists. In attempts to follow the work in our laboratory, Dr. Kendall has sent us specimens of his medium. If his surmise is correct, the entire structure of our attitude toward the biology of disease must be changed. It is almost as important as the theory of spontaneous generation, and nothing short of absolute proof should be accepted or we may risk making research even more difficult than it already is. In following Dr. Kendall's work, my associates Dr. Seastone and Miss Blumer have come to believe that the medium does not consist of unchanged protein, as stated by Dr. Kendall. The material is treated with alcohol and benzene for considerable periods, and it is reasonable to assume, therefore, that the protein is altered. The protein is certainly changed as regards solubility. We cannot get it back into complete solution, and many of the tubes show considerable turbidity. Also, because of the varying amounts of insoluble material in individual tubes, the titer of such tubes varies within the same lot. In his report today, Dr. Kendall has not gone further than he had when his first paper was printed. If his conclusions are correct, he has brought about a revolution in bacteriology, but we do not believe that he obtained the organisms from the filtrate after repeated invisible cultivation in the K medium. In his report today, he did not state that he had recovered the original organism. Errors of sterilization are hard to avoid with a medium of this kind and filtration itself is a complicated process. We have found the Kendall material a much poorer one than ordinary broth. In regard to filtration, difficulties may occur dependent not only on reaction and on the grade of filters and the negative pressure but also on the nature of the medium in which the organisms are subjected to filtration. It may be said that there is no measure of a filter except filtration itself, and the permeability of filters varies individually. In our laboratory some years ago Dr. Grinnell found that if old cultures were filtered in broth suspensions under proper control, almost all our filters would let through bacteria which did not come through in salt solution suspensions. Also, control cultures from filtrates would often show growth only after eleven or twelve days' incubation. We interpret this as a result of the passing through of bacteria or bacterial fragments, and not as cyclic changes. If a divided earthworm can regenerate to some extent, why should not fragments of bacteria, which divide by amitotic reproduction? Under particular conditions most bacteria can, in this way, pass through filters. To prove Dr. Kendall's thesis we must hold ourselves to certain postulates which we have published. We must filter a pure culture through a filter which holds back the original organisms and obtain signs of growth of the invisible forms in the special medium. The original organisms should not appear in the filtrate cultures after incubation of two to three weeks, if cultures are made on mediums suitable for the species of organism used. The invisible forms must be carried along for several generations. It must be possible to recover the normal forms after successive invisible generations by ordinary methods. We must not under any circumstances confuse the mere passage through filters of occasional bacterial cells with a filtrable cycle of bacterial life history. I wish Dr. Kendall's surmise were true and could be proved, but at present it is dangerous for the progress of bacteriology to accept this work until it has been satisfactorily demonstrated. This theory must not be accepted until it can be as rigidly proved as was the nonexistence of spontaneous generation. As to the supposed relationship of the filtrable forms to the filtrable viruses, that question is a still more complex one. I shall let Dr. Rivers speak on that point. I believe that there is a fundamental difference between the filtrable virus group and bacteria in physical characteristics, in pathology, in immunology, and in the clinical manifestations of the diseases to which they give rise. In conclusion, I feel that, as far as I can see, there is no fulfilment in Dr. Kendall's work of the criteria by which alone the correctness of his surmise can be demonstrated. We must continue to demand rigid proof and try to show ourselves wrong before we can accept these theories to be correct.

Dr. T. M. Rivers, New York: Dr. Kendall's ideas are interesting. The idea, however, that filtrable stages occur in the life cycle of bacteria is old. The idea that this represents a virus is not a recent conception. Nicoll, Kraus and others have advanced these theories. Dr. Kendall has used a new medium. This is of particular interest because the K medium is suggested as being suitable for the cultivation of a virus. There are two problems to be considered. Does the K medium show that bacteria have filtrable forms? Do the filtrable forms of bacteria represent poliomyelitis, vaccinia, and so on? Is this medium suitable for their cultivation? The K medium seems to me to be starvation diet for bacteria. Does a starvation diet cause the nonfiltrable bacteria to become granular, pleomorphic and filtrable? Does the diet change the ordinary characteristics? Another problem is the relation of filtrable forms of bacteria to virus. No one has brought convincing evidence that filtrable virus exists in the absence of living tissue. This suggestion was tested in regard to vaccine and to infectious myxomatosis of rabbits. A meat infusion was made of peptone broth with inoculation of the virus, incubated at 30 and at 37 C. Serial transfers of the cultures were made to fresh mediums. Titer was established by animal experimentation. Multiplication of the broth virus occurs with bits of living tissue but not in any of the other mediums. After a second transfer the virus was reseeded in meat infusion, peptone broth and then in K medium. Dr. Kendall says it is invisible in K medium. I tested this. I attempted to make highly active material, free from bacterial contaminations. After cultivation for two weeks, examination for minute colonies of bacteria gave no evidence of any kind of organism. From the results of this work and the analysis of Dr. Kendall's there is no reason to suppose that the K medium will support the virus or that its use will shed light on the particular agents.

Dr. William H. Welch, Baltimore: However erroneous the interpretation may be of these theories, the fact remains that the observations of Dr. Kendall mark a distinct step forward. As Drs. Zinsser and Rivers have pointed out, bacteria may form granules. That is a very old observation. Perhaps the greatest discussion was in connection with the cholera bacillus. They never determined whether granules were carried in the living bacteria. Dr. Kendall has brought evidence that the much discussed granules (from the disintegration of the cholera or comma bacillus) are capable of growth. This was never done before. Therefore this observation marks a distinct advance in knowledge.

Arthur I. Kendall, Ph.D., Chicago: The K medium is crude. That is beyond question. If I understood Dr. Zinsser correctly, he said that I had not recovered the organism in the urine after the filtration. Perhaps I did not make myself clear on that point. I did get the staphylococcus and the streptococcus back. The staphylococcus was a characteristic one, and the streptococcus before and after the filtration was the same kind, as judged by fermentation reactions, as the one observed in the filtrable state. This seemed to show that the bacteria had been passed through the filters and then got back again to the original state in which they were filtrable and suitable for cultivation. I did not mean to raise a comment about filtrable virus. Apparently Dr. Rivers has succeeded where Dr. Zinsser was unsuccessful. I have in the laboratory a culture of typhoid bacilli that was passed through the filter, November 2; this has been in K medium up to March. It grows slightly but distinctly in the medium and it is possible to bring it back to the typhoid bacillus state, but it cannot be stained by any stain or cultivated in ordinary medium and it is invisible under the microscope. I have been interested in bacteria many years. I have been playing with them for about thirty-two years. I am not surprised that a great many have not succeeded in reproducing these things I have told about. The phenomena are different from anything I have seen before. These organisms have to be coaxed back. They have lost the ability to grow in ordinary laboratory mediums. Whether these forms that do pass filters grow in these conditions, whether they do, or do not, fulfil all the criteria as we know them of what filter-passing organisms are, is, I think, probable. For fifty years bacteria have been rather a puzzle, and we are not yet in a position to state definitely what science has failed to reveal to us in all this long time. In regard to the question of priority, which has been raised, that bacteria may pass filters is a modern idea; but if you want to know the original man who discussed the possibility of germs existing in two forms, read Lucretius, who in 50 B. C. wrote of germs existing in two states, one of which was insoluble.

Experiments on Active Immunization in Poliomyelitis

Dr. Simon Flexner, New York: This topic is not new. Experimental active immunization in poliomyelitis has been known since 1910. What I have to say relates to extension and modification of experiments that have been made in the intervening years. There is no doubt that the epidemic of 1930 has added stimulus to experimental work. The virus was obtained from human cases of 1909, the so-called mixed virus of the Rockefeller Institute, which is nearly 25 years old. It has been passed through monkeys for twenty-five years. The monkeys are inoculated intradermally. The animals develop a high immunity. Of four inoculated, all but one came through without symptoms; one developed symptoms and recovered. Two types of immunization were tried; a constant virus was tested against a varied serum, the latter a large amount. Then four animals which showed no symptoms were sprayed daily with instillations of virus in the nares, which is an effective way to introduce the disease. Without any lesion of the mucous membrane, all four animals developed fatal poliomyelitis. This virus has been permanently modified. It is immunologically not identical with the human strain, but it is not completely different. A type of virus from New South Wales, from patients' serum, is different from the American virus. Some doubt arises, therefore, whether active immunization is possible or desirable. Another question is whether it is possible to produce active immunity in monkeys. Immunity can be raised by injections given to recovered monkeys of a reinforced monkey serum, that is, a glycerolate of cord emulsion. This is the method of immunization of swine against hog cholera, and protecting dogs against distemper.

We have also tried to modify the virus so that it can produce immunity without causing paralysis. These experiments have to be carried much further. Not every batch of the material shows either antigenic purpura or infectious purpura, but if one can determine some degree of infectious purpura, that material in the skin of monkeys will give rise to immunity. It is an expression of neutralizing antibody giving resistance to intranasal injection.

It is certain that the virus passed through many monkeys has altered. It is more effective for monkeys. We cannot tell whether it is more effective for human beings. The next step will be to see whether it is more or less effective for anthropoids. Plenty of human volunteers are available but I think we are some distance from that yet.

The Early Use of Convalescent Serum in Poliomyelitis, Before Paralysis Has Developed: Comparison of Treated and Untreated Cases

Dr. William H. Park, New York: This study was a cooperative effort of the department of health, the department of hospitals, and a committee of the Academy of Medicine, to make potent convalescent serum available for therapeutic use, and, if possible, to evaluate the results. The cases were first reported to the health department laboratories; then the patients were visited by an experienced diagnostician. If the case seemed suspicious, spinal fluid was removed and sent by messenger to the research laboratory. If the diagnosis was confirmed, the patient was either sent to one of the hospitals, or was quarantined at home. If the family physician desired to have convalescent serum administered, one of the pediatricians from the Academy of Medicine was summoned. The average age of the treated group was about 6.5 years, and of the untreated group about 5.5 years. The average time of the administration of the serum was 1.6 days after the first meningeal symptoms. There was no definite indication that earlier treatment as compared with later treatment reduced the consequences. The antipoliomyelitis horse serum produced excessive meningitis when given intraspinally.

Observations on Poliomyelitis, with Particular Reference to So-Called Abortive Poliomyelitis

Drs. John R. Paul and James D. Trask, New Haven, Conn.: Epidemiologic studies on poliomyelitis, made in New Haven during the summer of 1931, indicate that cases of so-called abortive poliomyelitis may be of greater numerical importance than has hitherto been suspected. Our attention was primarily directed to this fact during the recent local epidemic by the appearance of many examples of mild illness characterized by signs of a general infection, such as fever, headache, vomiting or perhaps sore throat, but not by signs of meningeal or myelitic involvement. Such minor illnesses recall the picture originally described by Wickman to designate his "abortive types" of poliomyelitis, and they also reflect Draper's concepts of the first phase of the so-called dromedary form of the clinical disease, which, he believes, probably occurs more often alone than otherwise. As present usage of the term "abortive poliomyelitis" is ambiguous and is employed by some to designate those cases in which signs of meningitic and myelitic involvement are present but in which no paralysis develops, we have employed instead the term "characteristic minor illnesses in association with poliomyelitis." In our study of 222 families from each of which one or more cases of frank poliomyelitis had come, it was found that these minor illnesses developed in about 40 per cent of these patients' siblings (under the age of 15 years) more or less contemporaneously with the appearance of a frank case within the family. Control families showed a 10 per cent incidence of these minor illnesses among children of the same age during the epidemic period. The age distribution of those attacked with minor illnesses was quite similar to those attacked by frank poliomyelitis. In a study of three communities, during the local epidemic, the incidence of these minor illnesses proved to be about six times that of the frank cases of poliomyelitis.

Twelve attempts were made to isolate the virus of poliomyelitis, by the monkey inoculation test, from the throats of patients with characteristic minor illnesses on various days of the disease. Two of these attempts were successful. The virus was obtained from a single attempt made on the first day of a minor illness and in one of four attempts made on the second day. Four attempts to isolate the virus from the throats of healthy contacts proved negative.

The observations bring further evidence to bear that mild and unsuspected examples of poliomyelitis may be of major import in the spread of this disease.

DISCUSSION ON POLIOMYELITIS

Dr. Simon Flexner, New York: My personal experience is wholly with the experimental disease in monkeys. There the use of immune serum does make a difference. As between human beings and monkeys, the conditions are not identical; but the advantage is in part with the human beings. The more inclusive the cases recognized as preparalytic poliomyelitis are, the higher is the proportion that escape detectable paralysis. Probably, in part at least, the lower mortality of the epidemic of 1931 is accounted for by the greater skill in diagnosis. There is therefore an inherently effective agency at work in aborting poliomyelitis in man. This agency is far less effective in monkeys. The experimental disease in these animals is rarely abortive (although many resist weak, unadapted virus strains), but it tends to be far more severe and fatal in monkeys, which do not have the uninoculated disease, than in man, who does. The severe form of experimental disease in monkeys can be prevented or mitigated by means of immune serum. Since the practice of medicine is applied to individual cases of disease and does not, except statistically, deal with disease in mass, the question may fairly be asked whether the preexisting mechanisms in man tending to confine and abort the virus infection cannot be supplemented and fortified by convalescent serum in some instances, I do not think this question can now be answered in the affirmative, and I equally do not believe that it can be answered in the negative. It is generally agreed that the use of human convalescent serum does no harm. Since it cannot be affirmed that, in an individual case, it does no good, should its use be withheld? That is a question to be answered not by the pathologist but by the practitioner. If a better, more calculable, method of preventing the paralysis were known, that is, a surer way of supplementing the normal mechanism which tends to restrain the action of the virus of poliomyelitis before it injures functionally the motor nerve cells, no question, such as I am presenting, would arise. However, there is no better and more calculable method known. The choice is therefore between no therapeutic intervention at all and a kind of therapeutic intervention believed to be harmless and not known actually not to be sometimes useful in cases of this tragic disease.

Dr. William H. Park, New York: In the opinion of the workers of the state department of health, the serum did not do any particular good. However, there is another way of looking at the matter, as Dr. Flexner has pointed out, and that is a personal one. I should like to put the question to every man here, If it was his child that had poliomyelitis, would he or or would he not give the serum?

Epidemiology of Typhus Fever and the Possible Evolution of the Rickettsia Disease Group

Drs. Hans Zinsser, Herman Mooser and M. Ruiz Casteneda, Boston: Typhus fever differs according to locality. That in Mexico is different from that in Europe. In both localities, susceptible rats and mice act as the animal reservoir. They are infected by ticks, bedbugs, rat fleas and rat lice. The flea is the most likely carrier. The disease is carried to man by the close association of rat and man. In regard to lesions, the characteristic brain lesions found in the European type are also found in Mexico. In some countries a scrotal lesion is more common. Perhaps the scrotal lesion may immunize against the brain lesion. A certain immunologic relationship is found between strains in different parts of the world. In testing these, the most useful animal is the guinea-pig. It presents the characteristics of the disease as regards temperature curves, mortality, scrotal lesions and brain lesions. The types of disease giving scrotal lesions show a cross immunology. It is thought that perhaps different insect forms in different countries influence the strains and cause differentiation in types. However, the New and Old World types may, at times, approach each other with great exactness.

Rickettsia are able to survive in a considerable number of rodents, rats, mice and rabbits. The spotted fever type is most adapted to the life of the tick. It is highly infectious. The virus can always be rejuvenated by passing through man. In the Old World the disease is kept alive in lice-infested districts; in the New World it is propagated by rat fleas. Probably the rodent reservoir occurred first and the insect adapted itself. Studies seem to show that the louse-man cycle is later than the tick-flea-rat cycle. We also believe that the African virus and the Old World virus are similar, or the same thing.

Relapsing Fever and Rat-Bite Fever in the United States

Dr. Edward Francis, Washington, D. C.: Weller and Graham collected evidence of about fifty cases of relapsing fever occurring during the last few years in Texas traceable to tick bites received while visiting caves in Llano, San Saba, Mills, Travis and Denton counties. Ticks of the species Ornithodorus turicata collected in dry dust taken from the floors of caves in Mills County and San Saba County, Texas, and received in our laboratory conveyed relapsing fever, acquired in nature, to rhesus monkeys on which they fed. Six days after being bitten by ticks, the monkeys manifested an abrupt onset of fever lasting a day or two, followed by normal temperature for four or five days, then six similar pyrexial attacks and six intermissions, followed by spontaneous recovery. Spirochetes having a length about twice the diameter of a red blood corpuscle were found by dark field examination and in stained smears of the monkeys' blood at times of fever, but not between. Bedbugs which were infected with this strain in the laboratory by feeding on the tails of infected white mice were capable for six months after their last infective feed to infect white mice into which they were injected but were never able to infect healthy mice on which they fed every ten days during the six months. California reported in 1931 ten cases of relapsing fever of man, confined by demonstration of the spirochetes in the blood.

A boy, aged 6 years, had seven paroxysms of fever in thirty-seven days. Macular eruption, demonstration of spirochetes in inoculated animals, and cure of the patient with arsphenamine clinched the diagnosis. There was no actual history of rat bite but there was edema of the penis, which extended from a very small healed point. A small amount of fluid aspirated from a slightly enlarged left inguinal lymph node and injected into a white rat yielded a strain of spirochetes, which was carried through white mice, white rats and guinea-pigs. The organism was a short spiral having few turns, few in number, very active in dark field preparations of animal blood, showing flagella at the ends, and having a length about half the diameter of a red cell. Much time can be consumed in fruitless search of the patient's blood for spirochetes. Only once (Steiner) has the organism been seen in the blood of cases contracted in nature in the United States. Shattuck and Theiler injected the patient's blood into white mice and guinea-pigs. Lanford and Lawson injected a white rat with lymph node juice of the patient. Bayne-Jones injected a guinea-pig with a macule from the patient's skin. The blood of white mice examined by dark field frequently for fifteen days after inoculation yields the quickest and surest demonstration of the spirochetes. An eye accustomed to the slow backward and forward movements of Spirochaeta pallida may completely fail to grasp the significance of the darting progression of one short Spirochaeta morsus-muris.

DISCUSSION ON FEVER

Dr. Hans Zinsser, Boston: We made a search for typhus fever in rats in Boston, and found a considerable number of rats infected. We found that many rats suffered from rat-bite fever. Many of them had pseudo-encephalitis, and there was considerable morbidity among rats with rat-bite fever, so that it is surprising how few cases of typhus fever are reported among human beings.

Dr. W. S. Thayer, Baltimore: The seriousness of rat-bite fever was impressed on me in Rome in a case in which a child of a friend of mine was the victim. The child awakened with a sudden cry and was found with the finger bleeding. After this the child suffered from peculiar phenomena and became very ill. An associate of the Pasteur Institute was called in and he asked whether any rats had been noticed. The nurse then recalled that a big rat had been seen in the room where the child slept. The wound was reexamined and the scar was found to show the indentations of the rat's teeth.

Dr. W. W. Ford, Baltimore: With regard to rats in Baltimore, we have obtained the organism of rat-bite fever from rats and transferred the material to white rats, in our work on search for parasites. We have found a leptospirillum, trypanosomes, and the spirillum of rat-bite fever. The rats, however, serve mainly for demonstration purposes in teaching. Although a large proportion of rats are infected, cases of rat-bite fever are rare in Baltimore, and spirochetal jaundice is not observed.

Dr. Emanuel Libman, New Yoak: In rat-bite fever the chances of infection are numerous, but the cases of fever are unusual. I saw two cases thirty years ago. Since then I have seen no cases in New York.

Dr. George Blumer, New Haven, Conn.: The first case of rat-bite fever that was reported was in 1830. Recently in the library at Yale I found notebooks of the students of Eli Ives, an early professor. In his lectures it was stated that the bite of the rat was dangerous under certain circumstances, and a satisfactory account was given of all the symptoms of rat-bite fever, which was noted thirty years ago.

Dr. Edward Francis, Washington, D. C.: We don't find many cases, and there have been no instances in which the spirochetes were found in the patient. They have been recovered in inoculated animals but not in man. The only way to get the spirochetes is to inoculate experimental animals.

Dr. Walter R. Steiner, Hartford, Conn.: In a report I presented to the American Climatological and Clinical Association, I thought that I had found an organism which was a spirochete. I was unable to cultivate it. It was immobile, and I found that instead of being a spirochete it was a spirillum. I had a photomicrograph made of the organism.

Dr. Francis G. Blake, New Haven, Conn.: Previous experiments in animals have suggested that basic active immunity to pneumococcal infection may depend on common antipneumococcal species rather than on type-specific antibodies. To test this theory the titer of antipneumococcal species agglutinins has been determined in the blood serum of 887 individuals from birth to old age, and the cumulative percentage curves for each of the titers found (0 to 1:10,240) have been compared with morbidity rates of the different types of pneumococcal pneumonia according to age. Since these curves seem to show a significant relation between low agglutinin titer and morbidity, the work has been pursued further by studying the course of subcutaneous pneumococcal infection in two groups of guinea-pigs, those with and those without species agglutinins in the blood. None of the animals in either group had detectable type-specific agglutinins in the blood serum. Following subcutaneous injection of 0.5 cc. of a saline suspension of virulent type-specific pneumococci, guinea-pigs with antipneumococcal species agglutinins showed a transient mild inflammatory reaction with a duration of from twenty-four to ninety-six hours, with prompt recovery, while those without species agglutinins showed a severe spreading cellulitis with a duration of from seven to eighteen days, frequently with hemorrhage, necrosis and ulceration, and with death in a considerable proportion. These results are in harmony with the view that basic active immunity to pneumococcal infection is a broad antipneumococcal species immunity and that the titer of species agglutinins may be a rough measure of susceptibility or resistance.

Advances in Serum Therapy of Pneumonia, Meningitis and Scarlet Fever

Dr. Augustus Wadsworth, Albany, N. Y.: The bacterial incitants of infectious disease differ markedly in virulence, in their parasitic adaptation to the tissues of an animal, in the potency of the toxins which they produce, and in their immunizing action. These capacities of the micro-organisms determine not only the chararter, extent and course of the disease processes but also the potency and valence of the therapeutic serums that are prepared from them. From the beginning, the quality of the antipneumococcus, antimeningococcus and antistreptococcus serums that have been generally available has varied greatly. While definite improvement has resulted from the establishment of federal and (in New York State) state control and supervision, the distribution of unsatisfactory serums has not been altogether eliminated. The practice of concentrating serums of low potency is commercially profitable, but unless the method is used solely to improve the quality of serums of the highest potency attainable there is no practical advance.

A total of 853 cases of type I pneumonia, treated with unconcentrated serum of the highest potency, had a mortality of 12.4 per cent, which, with the elimination of cases unsatisfactorily treated, approximated the mortality in Dr. Rufus Cole's series of cases at the Rockefeller Hospital; namely, 10.9 per cent. With antimeningococcus serum, a mortality of 18.4 per cent was recorded in a series of 742 cases of meningococcus meningitis. Favorable results were obtained with a monovalent unconcentrated antistreptococcus serum in the treatment of scarlet fever, erysipelas and other forms of streptococcus infection. A mortality of 4.3 per cent was reported in 1,052 cases of scarlet fever, of which 402 were classified as severe, 441 as moderate, and only 209 as mild. The mortality of the 194 cases of erysipelas was 8.2 per cent, and the serum appeared to be quite as effective in this disease, although, in a few instances, the serum, so far as could be ascertained, had no effect, indicating the importance of the selection of the strains and of a broad valence as well as a high potency in the serum.

DISCUSSION ON IMMUNIZATION

Dr. William H. Park, New York: Dr. Ross is trying to immunize human beings by feeding pneumococci of types 1, 2 and 3. Only 1 per cent may have type 1. I think there is great variation in individuals so far as the mouse potency test goes.

Dr. F. T. Lord, Boston: Dr. Wadsworth has spoken of the problems of the laboratory. There are also practical problems in putting the product into circulation. In Massachusetts there are technical difficulties which confront the doctor. These difficulties have to a considerable extent been overcome in Massachusetts in respect to meningococcus pneumonia by an organization which deals from a central source in cooperation with the physician. The state commissioner of health has control of a grant to provide serum treatment for cases of pneumonia. Through this generous grant from the commonwealth we have been able to carry on satisfactorily. The School of Public Health at Harvard studies the epidemiology of the disease. The White antitoxin and vaccine laboratory of the state standardizes the potency of the serum after the method of Felton. We have also funds enough to cover the clinical work in the state. There is a state advisory committee. There are eleven areas in which we have set up a pneumonia service. In each of these centers we have technicians trained in pneumococcus typing, and connected with the advisory committee we have three or four physicians practicing in each area. The concentrated pneumococcus serum is given to these physicians, and the physician may call in consultation, if he wishes, a man from the laboratory to give the serum. We have accomplished one thing. We have made a short disease of lobar pneumonia, and we have eliminated a large number of the cases. The dosage given is 5 cc., 25 cc. and then 45 cc. at intervals of two hours. We do not yet know what the ideal dose is. This program has been carried out for eighteen months. The clinical records are being filled out and returned to us. We have records of eighty-nine patients treated before the fourth day. The mortality record is 12.3 per cent.

DR. AUGUSTUS WADSWORTH, Albany: My reason in presenting this paper was not to urge general use of antistreptococcus serum, although that is our ultimate aim, but to stress the importance of a thorough, painstaking investigation of the different strains of streptococci. When we obtain a serum of practical value, it will be made available for distribution.

Isolation of Spirochaeta Pallida from the Lesion in Gastric Syphilis

DRS. HUGH J. MORGAN and SEALE HARRIS, JR., Nashville, Tenn.: *This article will appear in full in* THE JOURNAL.

Reaction of Immune Rabbits Toward Reinoculation with Heterologous Syphilitic Virus

DRS. ALAN M. CHESNEY, THOMAS B. TURNER and FRANKLIN H. GRAUER, Baltimore: It has been established by several groups of workers that rabbits, during the course of an experimental syphilitic infection, acquire a resistance against the particular strain of spirochetes with which they were originally infected, and that this resistance persists after intensive treatment with arsphenamine. It has also been shown that this resistance is oftentimes not effective against heterologous strains of spirochetes obtained from different sources. Hitherto this resistance has always been tested by inoculating the animals by subcutaneous or intratesticular injection, a method that is favorable to the inciting agent and does not resemble the usual mode of infection in man. It was found that the resistance which develops in rabbits during the course of syphilitic infection is not effective against heterologous strains when the reinoculation is performed by dropping the inoculum on an intact mucous membrane surface, thus more closely simulating the natural conditions of infection in man. Even under conditions closely simulating the usual mode of inoculation in man, the resistance is found to be strain-specific, not species-specific. The extreme rarity of second infections in man, as pointed out by Kolle, suggests that in the case of human beings acquired immunity to syphilis is effective against heterologous strains of spirochetes, a condition that does not hold true for rabbits. If this discrepancy in the behavior of the two species (man and rabbit) toward heterologous strains really exists, as appears to be the case, it is necessary to be cautious in applying wholesale to human syphilis the results of study of immunity in the experimental infection in rabbits.

The Contagion of Tuberculosis

DRS. EUGENE L. OPIE and F. M. MCPHEDRAN, Philadelphia: We studied a group of families with histories of tuberculosis. We divided them into (1) sputum positive, (2) sputum negative, (3) suspected cases and (4) no member with tuberculosis. Our tests included repeated sputum examination, roentgen examinations, clinical examination and tuberculin tests. We found that there were many latent unsuspected cases in which tuberculin tests were the only evidence, although some patients showed roentgen changes. Latency represents the preclinical period of tuberculosis. This represents a serious problem, as all manifest tuberculosis is preceded by a period of latency. Marital contagion is a frequent source of exogenous infection. Adolescents often become reinfected in the home. On consultation, 12.4 per cent of patients were sputum positive and 4 per cent sputum negative. There was latent apical tuberculosis in 35 per cent. A wife with a sputum positive husband is very likely to acquire tuberculosis. Age is an important factor; adolescents are very likely to acquire contagion.

DISCUSSION

DR. F. T. LORD, Boston: There would appear to be a very important corollary to this work, which I believe Dr. McPhedran would endorse, and that is on discovery of a case of tuberculosis it is extremely important to examine the family. The state of Massachusetts has been conducting a ten year program of the skin testing of school children. The reaction is present in 27 per cent of our school children. There is 1 or 2 per cent of childhood tuberculosis and 1 in 1,000 present the familial type of tuberculosis. It is extremely important for the health of children that we discover tuberculous families. We must discover not only the infected child but also the source of his infection. Bovine tuberculosis plays a minor rôle in adults.

DR. WILLIAM H. WELCH, Baltimore: Infection with tuberculosis in childhood is not comparable with marital infection. I should like to ask Dr. McPhedran about this point. I think these are significant observations because they indicate that cases of tuberculosis in adult life are the result of reinfection. They are supposed to be due to lowered resistance lighted by infection already existing. Marital partners had already been infected. Are these reinfection with bacilli from an infected partner, or is it a case of lowered resistance without new infection? Marital tuberculosis should be considered quite apart from the tuberculosis of childhood.

DR. HAVEN EMERSON, New York: I think the great significance of Dr. McPhedran's communication is in regard to the question of reporting the disease. Half the active cases of tuberculosis are not known and 29 per cent are not reported at all until within one week of death, or even after death. Fifty-three per cent are under no kind of sanitary supervision. In Boston I took a group of fifty active cases in which the patients had in the aggregate been exposed to infection for 1,500 years. These fifty patients had, in their own homes, been known to be from six to ten years in contact with tuberculous infection. The gap between our knowledge and our practice is becoming wider. Our authorities lag further and further behind in preventive work. One means that can be used is repeated examination of school children. We are now examining 500 school children in three hours, at a cost of 75 cents apiece. That is making a beginning. We get an exact examination of the chest. But that does not protect the child. The failure to protect the child when a case of exposure to infection is discovered is the colossal blunder of the public health movement of today.

DR. F. M. MCPHEDRAN, Philadelphia: Dr. Lord has pointed out the necessity of searching for the source of infection when a diagnosis has been made. This is very important. Dr. Welch has spoken of exogenous infection. This is an interesting point. From a study in Philadelphia over ten years, I think that half the cases present reinfection. There is no doubt that adolescent tuberculosis is due to reinfection. With high counts in the sputum, these patients go down very rapidly. I have found that in Italians the resistance is good. In some districts 75 per cent of the population is Italian. When controlled by figures among the Jewish population, I found about the same proportion of cases. The question of preventing continued infection is the crux of the whole matter. It is necessary to distinguish between sputum positive and sputum negative tuberculosis. In the children of grade school age, tracheobronchial infection has been made reportable. After one has got past the grade school, one can trace the source to the family, but one can't do much. In the high school age one gets lesions of immediate significance.

Plasma Proteins in Patients with Anemia

DRS. CHESTER S. KEEFER and WALTER K. MYERS, Boston: We do not see much edema in patients with enemia. We therefore examined the blood plasma of twenty-six anemic patients to see whether there was reduction of the plasma proteins. These cases included anemia from malnutrition, pernicious anemia and anemia due to loss of blood. The hemoglobin examined ranged from 12 to 60 per cent; the red blood cell count was from a half to three million. We sought to find whether there was any relation between the hemoglobin and the presence of edema but found no connection between the two. There was also no relation of the total proteins and the hemoglobin. We found that the total proteins were related to the edema. When edema was present, the total proteins were below 5 per cent. If the total proteins were above this there was (with few exceptions) no edema, either while the patients were in bed or when they were walking about. In some patients with low proteins, however, there was no edema. We found that there was no relation between blood loss, as from trauma, and edema. Our studies showed that with restricted protein intake, causing malnutrition, there was tendency to edema and low proteins in the blood.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Action of Certain Drugs on Nictitating Membrane. A. Rosenblueth, Boston.—p. 443.

Effect of Fasting on Activity of Skeletal Muscle.—Leese and his associates made a study of the effects of fasting on the activity of the artificially stimulated intact gastrocnemius muscle of the anesthetized rat. The phases of activity studied were the number of stimuli required to produce fatigue and the amount of work done by the muscle. The results indicate that fasting for periods of from 24 to 144 hours did not affect either the rate of fatigue or the total amount of work done by the artificially stimulated intact muscle. Studies were made on the glycogen content of liver and muscle from control and exercised animals. In all experiments, fatigue occurred before an exhaustion of liver and muscle glycogen. The amount of work performed by the muscle and the rate of fatigue were found to be independent of the amount of glycogen present in liver and muscle at the beginning and at the end of the experiments.

Specificity of Pancreatic Lipase.—Cherry and Crandall report that following obstruction of the pancreas in dogs an olive oil splitting lipase appeared in the blood in large amounts; there was no significant uniform change in esterase as measured by hydrolysis of ethyl butyrate or tributyrin. This is interpreted as evidence of the specificity of lipase; it is suggested that this term "lipase" be reserved for the enzyme (or enzymes) capable of splitting true fats and oils, and that the term esterase be used for the enzyme (or enzymes) acting on the simple esters. Lipase (olive oil splitting) was found in significant amounts only in pancreas, intestinal mucosa, liver and spleen. All tissues studied contained an esterase. A study of the activity of pancreatic and liver extracts and blood serum on twenty-one different esters gave no evidence of specificity other than that indicated by the absence of activity toward olive oil in certain tissues and its presence in others.

Insulin in Tissues Other than Pancreas.—Using a method of extraction which yields maximal amounts of insulin, from pancreas, Best and his associates were unable to demonstrate the presence of an antidiabetic substance in other normal tissues from the dog or ox or in the tissues of diabetic dogs. Positive results previously reported they believe can be attributed to one or more of several factors, each of which they discuss. Certain experimental results that have indicated a wide distribution of an insulin-like substance in the plant kingdom were not confirmed.

Action of Epinephrine and Parasympathetic Drugs on Intestine.—Bernheim and Blocksom describe experiments in which they demonstrated that epinephrine added to the ileum of a guinea-pig which has been contracted by pilocarpine or physostigmine causes a further contraction, which may or may not be followed by relaxation. After histamine, epinephrine always causes relaxation, but the relaxation occurs after a definite latent period. The relaxation is more rapid and the latent period shorter in the presence of nicotine or atropine. These facts indicate that epinephrine may act as an adjuvant to parasympathetic drugs and that its action is dependent on the amount of parasympathetic stimulation.

Digestive Leukocytosis.—Garrey and Butler are of the opinion that the low basal leukocyte count of the resting state is unaffected by the intake of large quantities of either protein or carbohydrate. Sudden distention of the human stomach, or abrupt changes in gastric temperature, due to hot or cold fluids, cause an immediate but mild and transient rise in the leukocyte count. Animal experiments indicate that these reactions are due solely to reflex vascular disturbances but have no relation to the absorption of digest. All experiments indicate that there is no digestive leukocytosis in normal adults.

Treatment of Involution Melancholia.—Seven patients with involutional melancholia were treated by Bowman and Bender with an ovarian hormone preparation. The method and amount of treatment varied. A careful study before and after treatment was made of the blood pressure, basal metabolism, blood chemistry (including nonprotein nitrogen, uric acid, cholesterol, fasting sugar and sugar curve), and the galactose tolerance. Two patients showed a good social recovery. Three patients were unimproved and now show a chronic picture. Two patients died, one of anemia and bronchopneumonia, and one of carcinoma of the uterus. The treatment, therefore, appears to have had little or no effect on the final outcome of these cases. In giving the ovarian hormone preparation, the authors had in mind the possible restoration of the menstrual cycle. The results were quite different. Except in one case, in which a very slight flow occurred on two occasions, the effect of treatment was to cause complete cessation of the menses. In three cases there was menstruation up to the time of treatment, but none after treatment started. In one case menstruation continued for two months after treatment and then ceased. One patient had had a panhysterectomy, so that no changes were possible. One had had the menopause eleven years previously, and treatment produced no effect. Very little change occurred in the blood chemistry during treatment. When such changes did occur, they were usually in the direction of a more normal condition. However, some patients did show disturbances in weight, arterial tension, and increase in nonprotein nitrogen not due to any apparent cardiorenal-vascular disease, a low blood cholesterol, disturbances in sugar curves, and low basal metabolism. These may all be favorably influenced by glandular therapy, especially the specific female sex hormone. Such therapeutic measures may improve the patient's general physical condition, alleviate distressing symptoms, remove abnormal sensations which may be feeding delusional trends, or shorten remissions, and in some instances are apparently associated with complete clinical recoveries.

Paranoid Reaction.—According to Stevenson and Montgomery, there appears to be a clinical subentity in the psychogenic or "reaction to environment" group of psychoses, in which the chief symptoms are persecutory delusions, with or without hallucinations, and without obvious personality or intellectual changes, occurring in highly moral women, and becoming apparent during the fifth and sixth decades after a long prodromal period, the change from normal to psychopathic being so gradual that relatives have found difficulty in fixing the date of onset, and persons who have but slight contact with the patient are not aware that the individual is suffering from a psychosis. A close study of many cases admitted to mental hospitals over a period of years has convinced the authors that there is a specific etiologic factor, among others common to the group as a whole. This so-called specific factor they believe to be an overt or imagined sinful act on the part of the patient, which is not sinful to the patient, however, as she either projects the blame on others or denies that it would have been consciously desired by her. The situation is thus not dealt with adequately and honestly, and a state of emotional unrest is produced. As a quietus to conscience, a persecutory delusional trend is developed slowly and progressively until a well marked psychosis results.

Traumatic Lesions of Abdominal Viscera. — Hinton urges an immediate laparotomy in cases in which one is reasonably certain of an injury to a hollow viscus from traumatism to the abdomen. If the diagnosis is questionable, however, through the symptoms being masked between those of a rupture of a solid organ, such as the liver, kidney or spleen, and retroperitoneal hemorrhage on the one hand, as against injury to a hollow viscus, it is to the patient's advantage to employ conservative methods of treatment rather than to submit him to immediate operation. If this principle is followed, one will have a lower mortality and morbidity in cases of injury to the abdominal viscera.

Recurring Omental Hypertrophy.—Probstein believes that primary hypertrophy of the omentum is probably not associated with any inflammatory condition, especially in view of the lack of microscopic observations to substantiate the term "omentitis or epiploitis," thereby suggesting a state of inflammation. This hypertrophy may be due to some circulatory interference rather than to an infection in which the omentum becomes enlarged, edematous and hemorrhagic. The term "omental hypertrophy" seems much more appropriate to the author in view of his observations than omentitis or epiploitis, which suggest the association of the pathologic changes with an inflammatory condition.

Oleothorax.—Matson calls attention to the fact that oleothorax therapy, although closely related to pneumothorax therapy, is a comparatively recent method of treatment and therefore lacks the test of time. Oleothorax therapy requires far more technical skill, keener judgment in the selection of material, and much more careful observation of cases than is required in pneumothorax therapy. Oleothorax therapy is indicated in the course of pneumothorax therapy under the following conditions: (1) as a disinfection oleothorax; (2) to inhibit the expansion of the lung in a threatened early obliterative pneumothorax, and (3) as a compression oleothorax to reestablish collapse, or for the purpose of collapsing rigid-wall cavities in which an intrapleural pneumolysis is impossible. Two types of oil are used, mineral and vegetable, to which aromatized oil is added in a strength of from 1 to 10 per cent. Mineral oil is less absorbable and less irritating than a vegetable oil. A mineral oil is recommended in order to inhibit expansion of the lung or for compression purposes. A vegetable oil is preferable in the toxic, mixed-infection empyemas, because its rapidity of absorption permits a penetrating action of the aromatized oil. It also possesses great nutritive value. Aromatized oil, in a strength of 5 per cent, is capable of killing the tubercle bacillus and is therefore recommended in the tuberculous empyemas. In the mixed-infection empyemas it should be used in a strength of 10 per cent, since weaker solutions are not able to destroy mixed-infection microorganisms. The fundamental principles of a disinfection oleothorax are (1) complete evacuation of the pus, (2) thorough cleansing of the pleural cavity, and (3) a disinfection oil-bath of the entire serosa. Oleothorax is not justified in the treatment of an ordinary pneumothorax empyema unless it tends to chronicity and toxicity. Any substance, even air, when introduced into the pleural cavity, is likely to act as an irritant to which the pleura responds with an exudate formation. For the reason mentioned, oleothorax therapy is not intended to supplant pneumothorax therapy, and it should be employed only when it is evident that a pneumothorax cannot serve its purpose. Oleothorax therapy is not recommended for the treatment of the ordinary serofibrinous exudates, which are well tolerated, for the reason that the oil may produce an inflammatory reaction, thus reawakening the exudative activities of the pleura. In the absence of a purulent exudate, one should never attempt an oil blockade of the pleural cavity without first having tested the sensitiveness of the pleura to oil. In converting a pneumothorax into an oleothorax, one should be careful not to disturb the intrapleural pressure. This is accomplished by injecting the desired quantity of oil and the aspiration of air in units of 20 cc. Before a compression oleothorax is established, the pleura should be prepared for higher oil pressure by preceding increased high air pressures. There is grave danger of lung perforation when a compression oleothorax is maintained under high pressure. Pleuropulmonary perforations are almost invariably due to progressive lesions in the lung cortex or pleura which ulcerate into the pleural cavity. The apparent increased incidence of pleuropulmonary perforation in patients undergoing oleothorax therapy is due to the fact that more cases are revealed by the oil. The presence of an unaccountable, gradual elevation of temperature demands exploration of the oleothorax cavity.

End-Treatment of Artificial Pneumothorax.—Dundee believes that in many cases the artificial pneumothorax treatment of pulmonary tuberculosis can be terminated more satisfactorily at home than at a sanatorium, because the reexpanding lung is best tested when the patient is in a normal environment and carrying on his normal work. The description and the end-treatment of certain different types of artificial pneumothorax are presented. In two types, phrenic avulsion, in a new capacity, is advocated to help obliterate the remaining pleural space, to prevent undue stretching of pulmonary scars and to diminish mediastinal retraction. Four cases are cited. All of these cases show a highly satisfactory response. The term "inner selective collapse" is used to describe a collapse in which the normal area of the lung is allowed to reexpand only 80 per cent. This method is recommended as preferable to "selective collapse" when the normal area of the lung is allowed to reexpand completely. The author condemns the practice of allowing moderate to large amounts of fluid to remain in the pleural cavity for prolonged periods, because such a procedure eventually tends to limit seriously the reexpansion of the lung, as it usually increases pleural thickening, pulmonary fibrosis and atelectasis. The benefits gained by allowing moderate to large amounts of oil to remain for a long time in the pleural cavity must be carefully weighed, as here also there is danger of excessive formation of pulmonary fibrosis and atelectasis.

Accessory Roots in Phrenic Exeresis.—Fisher analyzes a recent series of phrenicectomies, accompanied by careful search for accessory phrenics, with regard to the value of this procedure. In thirty-six phrenic exereses, one or more accessories were found in twenty-two cases, or 60 per cent. Five had multiple accessories, four being the greatest number found in any given case. In eight an accessory accompanying the nerve to the subclavius was found and resected. In one case a double phrenic was present, the two being of equal caliber, crossing the scalenus anticus and passing beneath the clavicle without uniting. Before exeresis of the main stem, resection of all accessory phrenic roots passing separately beneath the clavicle is suggested, as an aid to avulsion and as an additional safeguard against injury to the subclavian vessels. In the author's series, twenty-four phrenic nerves, or 66⅔ per cent, were completely avulsed by this method, the greatest length being 44 cm. In only one instance was less than 10 cm. obtained, in a patient who had been operated on a year previously in another institution without securing permanent paralysis; dense scar tissue rendered avulsion out of the question at the time of reoperation, although resection of an undoubted phrenic produced immediate immobilization and elevation of the hemidiaphragm. An appreciably larger incision is not ordinarily required in order to permit a search for accessories, although somewhat more thorough dissection of the deep structures and a little longer time are obviously necessary. In all the cases in the series, paralysis and elevation of the hemidiaphragm resulted.

Pulmonary Tuberculosis Simulating Chronic Adhesive Pleurisy.—According to Packard, pulmonary lesions alone may give all the physical and roentgenologic signs of an extensive adhesive pleurisy. Only by testing the pleural "space" with needle and manometer is it possible to tell whether there is pleural symphysis or not. Patients who present the physical and roentgenologic changes associated with an organized pleurisy should not be denied an attempt at artificial pneumothorax, if such therapy is clinically indicated. The author believes that artificial pneumothorax should be attempted before thoracoplastic operations.

Blood Sedimentation Tests.—Spector and Muether consider that the Rourke method is the most accurate blood sedimentation method yet devised for studying clinical as well as pathologic activity, and is superior to the thermometer or the total leukocyte count in this regard. The Cutler method is a practical method if the cell volume is within normal limits. The tests are not specific, as the sedimentation is rapid in other diseases, and do not give any information as to the extent of disease, except perhaps in a general way. However, they are of great aid in prognosis, and, diagnostically, in the sense that they detect infection. The modified Arneth method is just as sensitive in detecting early infection as any sedimentation test yet introduced. It is not as time consuming as either the Rourke or the Cutler method. The Schilling method appears to be inferior to the Rourke sedimentation test and the Arneth test. However, it throws more light on the question of resistance of the patient. The author's observations seem to suggest that a combination of the modified Arneth and the Schilling tests would give more information as to activity of the disease, prognosis, and resistance of the individual, than any of the sedimentation tests yet introduced.

Thyroiditis.—Clute and Lahey state that acute thyroiditis rarely occurs as a serious prostrating condition. It occasionally progresses to abscess formation and requires adequate exposure and adequate drainage. Syphilitic thyroiditis occurs as a diffuse thyroiditis or as a nodular gummatous thyroiditis. It is cured by antisyphilitic treatment. Tuberculous thyroiditis is found occasionally on microscopic examination of thyroid tissue. It has little clinical importance. Chronic thyroiditis frequently produces considerable constriction of the trachea with pressure symptoms and requires surgical relief. An operation such as removal of the isthmus relieves the constriction and does not produce myxedema. Myxedema is particularly apt to follow operations on the thyroid for thyroiditis.

Cardiac Features of Goiter.—Pemberton and Willius stress certain principles which in their experience have proved of definite value in the operative treatment of goiter in persons with cardiac disturbances. Owing to the fact that the margin of safety in many of the cases is exceedingly narrow, as sometimes the slightest mishap will mean the difference between success and failure, the need for the greatest possible care in every phase of the operation is obviously indicated. In the selection of the anesthetic and the method of its administration there are two considerations of extreme importance: 1. Since all the patients are more or less debilitated and, therefore, particularly susceptible to pulmonary infection, the type of anesthesia which is least likely to contribute to this complication should be chosen, and, unquestionably, prolonged anesthesia by inhalation should be avoided. 2. The anesthesia should be such that the patient can be awakened, in a reasonable state of comfort, after resection of the first lobe, in order that the functional integrity of the inferior laryngeal nerve can be determined. The value of this is obvious, and in the authors' opinion it is the most important single step in the operation. It has been their experience that combined anesthesia, namely, infiltration with procaine hydrochloride (0.5 per cent), supplemented by nitrous oxide and oxygen by inhalation, most nearly fulfils these requirements. Under this method, the average duration of the administration of gases is from eight to ten minutes. For patients with obstructive dyspnea, local anesthesia is definitely indicated. Not uncommonly, in cases of congestive heart failure, there may be circumstances relating to the condition of the patient or to the difficulties of the operation, such that performance of the operation in stages will materially minimize the hazard. Too often the surgeon is prone to believe that the outcome of an operation is favorably influenced to only a limited degree by any measure instituted after the patient has left the operating room, and it is true that a large proportion of these patients do not require any treatment other than symptomatic measures employed as a routine. However, not uncommonly grave complications develop, such as obstructive dyspnea, hyperthyroid reactions, pulmonary edema and infection, and since the successful treatment of these is dependent on early recognition of impending signs and prompt institution of proper treatment, close supervision by an experienced clinician is indispensable. It is for this type of complication, associated with cyanosis, that treatment by oxygen, preferably in the oxygen chamber or tent, has proved to be of great value.

Use of Potassium Iodide in Hyperthyroidism.—Frazier reports a series of cases of both forms of toxic goiter (hyperplastic toxic goiter and toxic adenoma), which were prepared for operation with potassium iodide. The general improvement noted, as well as the specific improvement in pulse and metabolic rate, paralleled the improvement obtained by compound solution of iodine. The clinical charts of several representative cases are exhibited which graphically show the preoperative response of thyrotoxicosis to potassium iodide. The author concludes from the evidence obtained in a surgical research laboratory that free iodine, to be absorbed, must be converted into an iodide, and from his clinical investigation, that it appears unnecessary to have free iodine "loosely combined," to which quality has been ascribed the effect of the administration of compound solution of iodine on hyperthyroidism.

Thyroid Crisis.—According to the Greenes, thyroid crisis is one of the most serious complications of hyperthyroidism. As a rule this condition occurs in the primary toxic, or exophthalmic, goiter. Thyroid crisis usually occurs in patients known to have hyperthyroidism but in whom no treatment has been sought or in whom inadequate treatment has been instituted. It may occur in individuals in whom there is no suspicion of thyrotoxicosis. A crisis may come on immediately after operation or several days later. Acute hyperthyroidism may be ushered in by physical fatigue, by psychic stimulation or as a result of an intercurrent infection, or may appear after some surgical condition often trivial. Measures not aimed to relieve the hyperthyroidism should be postponed until after thyroidectomy has been performed. Adequate preoperative therapy will in the majority of cases prevent postoperative acute thyroidism. The picture of crisis may appear suddenly with no premonitory manifestations, or make its appearance slowly with definite symptoms. The mechanism whereby a crisis is set into motion is not known. The condition must be recognized early and proper therapy instituted immediately or death will frequently result. Treatment consists of iodine, fluids, dextrose and morphine. After recovery from a crisis, surgical intervention should be done with caution and after one has waited long enough to get the patient in proper physical condition.

Arteriovenous Aneurysms: Effect on Heart.—Reid calls attention to the fact that arteriovenous aneurysms involving large vessels usually affect the heart. The main factor in the causation of the damage to the heart is the increased amount of blood that it has to handle. This results from the quick shunting of a large amount of arterial blood back to the heart. Another factor which is probably of importance is that there results a condition resembling aortic insufficiency, although the lesion may be far removed from the aortic valves. A case of femoral arteriovenous aneurysm, which had been present for seventeen years, is recorded. It illustrates many of the effects of this condition—cardiac hypertrophy and dilatation, Branham's bradycardiac phenomenon, disturbances of blood pressure (Hill and Flack sign), changes in the electrocardiogram, pulsating varicosities, dilated and atrophied proximal artery, capillary pulsation, very adequate collateral circulation, and so on. Excision of the aneurysm relieved completely all cardiac symptoms and caused the heart to return to a normal size. This case strongly supports the teaching of Matas that the heart should be prepared for the complete closure of the fistula by a preliminary period devoted to temporary occlusions of it. Although the abundant collateral circulation reduces to a minimum the danger of peripheral gangrene, the heart should be considered and partially adapted to the great and sudden change that will follow the operation. An intelligent patient who has practiced temporary occlusion of his own fistula is usually quite certain when it can be permanently occluded without causing any cardiac distress.

Cancer of Colon and Rectum.—Bloodgood emphasizes the fact that, in cancer of the colon and rectum, surgeons cannot with justice either to themselves or to the public assume that their responsibility begins with the preoperative preparation. The chief cause of failure to this condition is late intervention. Contributory causes are incomplete preoperative investigation in which the precancerous or cancerous lesion is overlooked by some member of the medical profession and valuable time lost. All physicians are apt to make the mistake of performing an incomplete diagnostic study before operation or an incomplete preöperative preparation. Apparently the least important factor in the failure to cure the majority of cases of cancer of the colon and rectum is the operative skill of the surgeon. This factor may be too large but it cannot be compared with the delay on the part of the patient and the failure to recognize an operable condition on the part of the general practitioner who does not keep up with modern diagnostic methods. Undoubtedly, in cancer of the rectosigmoid colon, surgeons of less experience and skill have too large a mortality. There should be no difficulty for them to recognize these cases clinically and back out either before any operation or after an exploratory laparotomy. In the latter event they can perform preliminary appendicostomy and save the patient much time. The author recommends appendicostomy preliminary to resection of every part of the colon except the right colon when the cecum is removed. His impression is that lateral anastomosis, when possible, is safer than end to end. In tumors of the rectum and rectosigmoid, pathologic studies and final results demonstrate that it is unnecessary for a cure to give the malignant tumor of the colon or rectum wide margins of intestine. The restricted operation should be chosen when possible, if it promises lessening of the operative risk. For the same reason, operation in stages should be chosen and blood transfusion freely employed. One should not wait for symptoms of shock but anticipate the collapse. Also, it should be remembered that the rectal tumor can be properly removed through the sacral route. It is possible to perform an abdominal colostomy if the sacral one is unsatisfactory. Many of the most experienced and best trained diagnosticians often curtail the preoperative diagnosis the moment something definite is found indicating surgical intervention. Many experienced surgeons, before operations on the colon, do not give the patient proper preoperative preparation. If there is obstruction, colostomy is indicated, which can be part of a preoperative diagnosis and preparation, because the obstruction must be relieved. The author recommends appendicostomy without exploration to determine the position of the tumor unless there are definite symptoms indicating the necessity of further exploration.

Bone Formation in Abdominal Wall Following Transplantation of Mucous Membrane of Urinary Bladder.—Abbott and Goodwin report the case of a man who developed an extensive sheet of bone in his abdominal scar following a two-stage prostatectomy. They also report the results of an investigation to determine the type of bony growth produced when the mucous membrane of the bladder or all its layers are transplanted into the abdominal wall. Up to the present time they have transplanted mucous membrane or the full thickness of the bladder wall into the layers of the abdominal wall in twenty-six dogs. It was found that, following the transplantation of the mucous membrane of a dog's bladder into the connective tissues of striated muscle, fascia and fatty fibrous connective tissue, an epithelium-lined cyst is formed. On about the twentieth day, bone makes its appearance next to the newly formed epithelium and reaches its highest point of development in about sixty days. The newly formed bone is strictly limited to the newly formed epithelium and never infiltrates the surrounding tissues. This in no way resembles the bony growths that occur in abdominal scars and heretofore have been classified as myositis ossificans. These are not cystic and are frequently of large size. At the present time there is no evidence that mucous membrane of the human bladder when transplanted into the abdominal wall will produce bone.

Liver Extract in Treatment of Pernicious Anemia.—McHenry and his associates present the results obtained when extracts prepared in the Connaught Laboratories of the University of Toronto were employed in a series of forty-three persons with pernicious anemia. The extract produced by this laboratory has been made by a standard method since April, 1928. The procedure employed is a modification of that developed by the Harvard group, and is as follows: Fresh beef liver is minced and extracted with water adjusted with sulphuric acid to secure p_H 5.0. The mixture is heated to 60 C., to coagulate the albumin, and filtered. The filtrate is concentrated in a vacuum still at low temperature. The concentrate is poured into sufficient alcohol to give a concentration of 55 per cent alcohol. A precipitate, shown by tests to be inactive, is removed by filtration. Sufficient alcohol is then added to the filtrate to give a concentration of 95 per cent. The precipitate thus produced is dried in a vacuum oven and pulverized. There would seem to be little chance of such an extract changing in potency from batch to batch, unless there is some seasonal or other variation in the individual livers. There is at present no evidence of any such change, and with the large number of livers used in each batch there would seem to be little likelihood of any such individual variation being great enough to affect the potency. Every effort has been made to standardize the procedures used in the preparation of this material and to prepare for distribution a homogeneous mixture of numerous individual lots. From this point of view, therefore, there is no reason to suspect any change in potency between the various lots of extract. During the year 1927, liver extract was prepared in these laboratories and distributed gratuitously. Since that time sufficient material for one month's treatment has been made available without charge to physicians who have suitable patients under their care and who are willing to cooperate in the testing. In cases in which it is not convenient for the physician to make reticulocyte counts, slides stained with brilliant cresyl blue are provided. Blood smears made on these slides by the physician before and every second day for two weeks after the beginning of treatment are returned to the laboratory, where the reticulocytes are counted. Hemoglobin determinations and red cell counts are made before and at regular intervals after treatment is started. In spite of numerous attempts to develop other procedures, the clinical test is the only reliable method at present available for determining the potency of the extract. Evidence of the constant potency of this extract is available from the results obtained in the group of forty-three patients on whom were tested various lots.

Coronary Thrombosis.—Oille emphasizes the fact that coronary thrombosis must be differentiated from angina pectoris. The pain of angina is less severe. It is frequently described as only a tightness, an uncomfortable feeling, or a compression or constriction in the chest on exertion or excitement. It lasts only a few minutes, rarely as long as half an hour. The pain of coronary thrombosis, on the other hand, tends to occur lower down the sternum, is more often bilateral, and is more widespread than that of angina. It is usually much more severe and lasts for hours or days instead of minutes. Patients with angina stop and stand still in the attack, while some patients with coronary thrombosis are restless and cannot remain in bed. In cases of angina the following distinctive features of coronary thrombosis are always absent—severe dyspnea, changes in pulse rate and blood pressure or heart sounds, vomiting, shock, signs of failing circulation, fever and leukocytosis. Electrocardiographic changes occur in angina, but they are temporary, lasting only a few minutes. The importance of distinguishing coronary thrombosis from angina is illustrated by the fact that the operative mortality in coronary thrombosis is six times as high as it is in angina pectoris.

Unusual Manifestations of Insulin Reaction.—Feigenbaum presents a case that demonstrates some unusual neuropsychiatric manifestations of an insulin reaction. Clinical and experimental evidence is offered to indicate that the nervous system is primarily involved in the symptomatology of an insulin reaction. An insulin reaction is not always accompanied by hypoglycemia, and it does not always respond favorably at once to the administration of dextrose. The dose of insulin administered usually determines the duration of the insulin reaction. The prognosis of a severe insulin reaction is good if the patient receives adequate treatment. The underlying mechanism of an insulin reaction still remains obscure.

Distention Following Abdominal Operation in Children.—Denney states that, by the use of diathermy, troublesome distention following abdominal operations may be controlled. This procedure is most useful in those cases in which, following rupture of the appendix, the distention and toxic state become pronounced and dangerous. There is no difficulty in its management. It causes the patient no physical or mental discomfort, even acting as a soporific. It can be used as often as is necessary, and adds no extra burden to the circulatory system, as may be the case when hypodermic medication is used. In those cases in which toxicity is marked, a saline-dextrose solution intravenously may be of assistance in overcoming the toxemia and increasing peristalsis.

Intracapsular Fractures of Neck of Femur.—According to Phemister, after intracapsular fracture of the neck of the femur the proximal fragment, which consists largely of head, may remain alive, receiving its nourishment through the internal portion of the capsule or round ligament, or it may die from interruption of the circulation. The percentage of cases in which it becomes necrotic is not definitely known, because of lack of studies on material derived from necropsy and operation and because of failure to utilize the roentgen rays in the recognition of necrotic heads. However, it is known that it dies in a considerable percentage of cases. In either event the fracture may unite or remain ununited, so that there is one of four conditions with which to deal: (1) a live head with union, (2) a live head with nonunion, (3) a dead head with union, and (4) a dead head with nonunion. As a result of the utilization of the knowledge of the pathology of these cases in roentgen interpretation it is usually possible to say after the lapse of several weeks from a study of roentgenograms whether the head has died or remained alive. It has been found that there is more or less creeping substitution of the dead bone by new bone. In the act of replacement of the dead head by living bone in the cases in which nonunion has resulted, new bone is formed from the invading connective tissue by metaplasia of the fibrous into bony elements. The roentgen determination of whether the head is alive or necrotic is based on the difference in density changes in the two conditions. If the head remains alive it shows a reduction in density as a result of atrophy of disuse during the period of treatment, and subsequently, if function is not restored to normal. If the head dies, it of course cannot undergo atrophy of disuse; and density changes result only from bony absorption by invading connective tissue and replacement by new bone. Absorptive and reconstructive changes in the necrotic head usually come about much more slowly and unevenly than is the case of atrophy of the living head. Consequently, in most cases it is possible to determine from roentgenograms taken after three months has elapsed whether the head has died or remains alive.

Quantitative Diets in Diabetes and Obesity.—According to Nadler, the conversion of the daily food allowance as expressed in grams of protein, carbohydrate and fat into food portions and their division into meals seems to be the chief obstacle to the more widespread use of quantitative diets. This relatively simple procedure has until recently been taught in few medical schools; even in hospitals it is usually left entirely to the dietitian, with the result that many clinicians have had little opportunity of calculating diets. Experience in teaching medical students has proved that this information is easily acquired by actual practice. All that is required is a table of food values, a food scale (marked in grams) and practice. Analyses of most of the foodstuffs used in this country can be obtained by writing to the Bureau of Records, Department of Agriculture, Washington, D. C., for Bulletin 28, by Atwater and Bryant, and enclosing 10 cents in coin. The simpler tables of food values prepared by Joslin and found in his invaluable Diabetic Manual serve admirably; in particular, one should memorize or have at hand a list similar to Joslin's table of caloric values for common foods as a basis for rapid calculation.

Surgery Versus Irradiation in Benign Uterine Hemorrhage.—From a review of the recent literature on the subject, Ochsner and Sullivan have come to the conclusion that there is a gradual swing toward surgery and away from irradiation in the treatment of these conditions. It would seem evident that when the number and frequency of complications are taken into consideration and all the contraindications listed by the various authors are scrupulously observed, the number of cases of benign uterine hemorrhage in which irradiation is indicated is very limited. The authors emphasize again the possibility of a persisting anemia and the danger of severe nervous disturbance following irradiation and the advantages of a modification (packing of the uterine cavity for two minutes with plain sterile gauze saturated with solution of formaldehyde-U. S. P.) of the Hill treatment for premenopausal bleeding.

Use of Thyroid and Suprarenal in Diatheses of Infancy.—According to Barbour, there is much clinical and laboratory evidence that the constitutional diatheses of infancy are manifestations of a neurochemical imbalance of the congenitally unstable physiologic activities of the infant. There is some pathologic and clinical evidence that this neurochemical imbalance is the result of a disturbed equilibrium between the secretions of the endocrine glands. Therapeutic results presented by the author for confirmation indicate that the endocrine dysfunction lies primarily in the thyroid and suprarenals.

Plantar Reflex.—Dosužkov believes that with regard to the plantar reflex there are two kinds of errors: those the result of a wrong examination and those the result of an incorrect appreciation of the rightly obtained facts. The anomaly of the methods consists in the following: (1) in an incorrect position of the patient during the examination, namely, with the flexed knee joint (when a plantar flexion of the toes displays itself even in cases of lesions of the pyramidal system); (2) in the using of an unsuitable tool for examination (mostly the handle of a neurologic hammer), whereby the positive Puusepp's phenomenon appears also in the healthy persons, and (3) in the examination of the reflex from the part of the foot-sole below the toes (whereby the positive Babinski phenomenon appears in the healthy person, too). The cause of errors in appreciating the results of the examination consists in the ignoring of the "physiologic Babinski," "peripheral Babinski," "pseudo-Babinski," "pseudo-Puusepp" and "pseudopathologic Babinski."

*Multiposition Bed for Continuous Postural Drainage. J. J. Singer, St. Louis.—p. 438.

Internal Drainage of Lung Abscess.—Dolley calls attention to the fact that it is chiefly among the cases of lung abscess in which the pneumonitis surrounding the abscess is still extensive or continues to extend that one finds the great percentage of operative deaths, and it is particularly for this type that he offers the following procedure: Its principle is based on continuous extrapleural pulmonary compression against the involved area in a direct line toward the draining bronchi to aid collapse and drainage of the lung tissue surrounding the area of liquefaction and necrosis without decreasing to any appreciable extent the intrathoracic coughing efficiency. The technic is as follows: The location of the abscess with its surrounding pneumonitis is determined by roentgen examination; the direction of the lobar bronchus draining the suppurative area is determined by bronchoscopy. A site in a direct line with the bronchus draining the involved area is located at the point where the abscess is nearest the lung surface. Under local anesthesia, short portions of three or even four ribs are excised together with their intercostal bundles, leaving for the floor of the wound the parietal pleura clear of muscle, vessels and nerves except for the periosteums of the removed ribs, which are left in situ. The parietal pleura is not freed beyond the limits of the wound, since too great collapse may interfere with bronchial drainage by the falling together of the smaller draining bronchi already softened by inflammation. The wound is packed very tightly with continuous five-inch dry gauze and is closed without drainage. The area deprived of rib sections is strapped tightly with adhesive plaster in order to restore as nearly as possible a solid chest wall or counterpressure in coughing. The wound is not opened for from fourteen to eighteen days unless infection demands it. It is then opened widely and the packing is removed. It is at once repacked with gauze saturated in some antiseptic solution and left wide open. The packing is changed every two days until rib regeneration has firmly occurred with the ribs in the compressed position. If the collapse obtained by this procedure is insufficient, at a second stage another adjoining area is deprived of its ribs to obtain further collapse, and still another stage if deemed advisable. Gauze compression, however, is limited to its original site. After the primary compression operation, further procedures are in the nature of well circumscribed thoracoplasties, and their number depends on the area required for collapse to produce continuous improvement to a cure.

Closed Endobronchial Anesthesia.—According to Gale and Waters, closed endobronchial anesthesia has been employed in several experimental animals for the removal of different lobes of the lung, and in one patient for the removal of a mediastinal tumor. Artificial respiration may be maintained in the one lung with perfect control of its respiration and minute-volume respiratory exchange. Intrapulmonary pressure is measured by a side tube to a manometer. The incorporation of the closed carbon dioxide absorption technic assures a warm moist anesthetic atmosphere at all times. The shock usually encountered on the sudden creation of an open pneumothorax has been slight. This has been demonstrated by the blood pressure and pulse rate remaining constant. The irregular and violent respiratory movements, so often seen, have been replaced by slow, regular and deep breathing. Exposure is simple for the surgeon because the lung in the operative field is immobile. Chances of infection are reduced because a sucking wound has been entirely eliminated. Little chance exists for infected secretions to be squeezed into the trachea because the bronchus is blocked. Although the method has been employed in a series of cases too small from which to draw conclusions, the evidence so far obtained gives promise that the closed endobronchial type of anesthesia is a most practical method to employ in intrathoracic operations in which the pleural cavity must be opened.

Multiposition Bed for Continuous Postural Drainage.—The advantages of the multiposition bed described by Singer are as follows: 1. Almost any desired position for use in postural drainage is obtained by little effort on the part of the operator and no effort at all on the part of the patient. 2. It permits one to carry out either intermittent or continuous postural drainage. 3. A regular standard bed is used with the fittings, which make them inexpensive.

*Mucocele of Appendix: Report of Case. C. Mayo 2d and J. U. Fauster, Jr., Rochester.—p. 254.

Tuberculosis of Larynx.—Nordland believes that resection of the superior laryngeal nerve is the surest method of removing dysphagia in patients with laryngeal tuberculosis. The operation presents no technical difficulties and does not cause any severe secondary phenomena. It can be done primarily on both sides and is easily borne by the patient. It has a definite symptomatic value and may have a curative possibility. The operation is suitable for other painful inflammatory processes in the larynx.

Mucocele of Appendix.—Mayo and Fauster review seventy cases of mucocele of the appendix. In their clinical analysis, no definite diagnostic point was revealed. The most significant facts are the history of distress and palpable mass in the right lower abdominal quadrant. With this present, mucocele of the appendix should always be considered. In uncomplicated cases, the condition is relatively benign. Although mucocele may be a primary type of malignant tumor, its growth is exceedingly slow, and complicating factors are rare. Rupture of larger mucoceles frequently results in the formation of pseudomyxoma peritonaei. The treatment in the uncomplicated case is appendectomy, and the prognosis is good.

Liquid Petrolatum as a Laxative.—Newman and Gruenfeld call attention to the fact that liquid petrolatum is emulsified in the intestinal canal and thoroughly mixed with the chyme. It constitutes a vehicle for the formed elements of the feces that cannot be absorbed. The therapeutic effect in constipation is brought about by the increase and maintenance of the volume of feces and possibly by a stimulation of the intestinal musculature during the emulsification and mixing of the oil with the chyme, especially in the cecum and ascending colon. Excessive quantities of the oil that cannot be emulsified and incorporated in the chyme are eventually transported into the distal portion of the colon as a liquid accumulation and may provoke peristaltic reactions which upset any therapeutic benefit.

Peptic Ulcer.—Emery gives the case histories of six patients with peptic ulcers of the jejunum and two with ulcers of the duodenum that he treated with roentgen rays. The results were satisfactory in four, questionable in two and unsatisfactory in two. In six there was an increase in pain for a week or ten days; the pain then subsided. In four there was a complete remission for a varying period of from six weeks to several months. Two patients continued to have pain, and in one of these a perforation occurred. In all the cases there was a drop in the acid, and temporary achlorhydria developed in four. It was observed that in six patients the amount of pain and acidity roughly paralleled each other. The author believes, as a result of his experiences with these cases, that roentgen therapy may be a useful adjunct to the treatment of peptic ulcer in a small, selected number of patients.

Copper and Iron Requirements in Infancy.—Bloxsom reports that the administration of copper in conjunction with iron for hemoglobin stimulation to a series of well infants showing a decrease in hemoglobin produced sufficient evidence of its value to make it worth while to report the results as a means of stimulating further study along this line. A series of fifty-seven infants were fed copper and iron daily in the form of copper sulphate and iron and ammonium citrate. This group of fifty-seven infants showed an average increase of from 5 to 15 per cent in hemoglobin over a group of 104 infants not receiving copper and iron. Copper is apparently a necessary element in the nutrition of the human body and must be supplied in sufficient quantities in conjunction with iron to the growing infant. The evidence presented in this study is in apparent accord with the experimental evidence in animals that there is a marked increase in hemoglobin when copper is added to a diet containing iron. The marked increase in hemoglobin response of infants given copper and iron apparently indicates that many infants suffer from a partial deficiency of these necessary elements in their early diets and that a substance rich in these hemoglobin regenerating factors may be of value as a routine addition to the diet after birth.

Insulin Fattening.—Nichol's report includes sixty-three cases, thirteen of which were reported in 1927. Forty-eight patients made satisfactory immediate gain with insulin, ranging from 5 to 30 pounds (11 to 66 Kg.). Of these forty-eight patients, twenty-three maintained their gain three months or less, eight for as long as six months, seven for one year, three for three years, and one for four years. Six cases were not followed. Many patients noted a tonic effect from insulin out of proportion to the gain in weight, making it difficult to tabulate the total effect of treatment.

Blastomycosis of Lungs.—Brooksher is of the opinion that primary fungous infection of the lungs is doubtless more common than is generally suspected. The possibility of such infection should be considered in cases presenting evidence of pulmonary tuberculosis but in which the tubercle bacillus cannot be recovered from the sputum. No characteristic physical, clinical or roentgenologic observations are noted. Further study roentgenologically may indicate in which chests a suspicion of its presence should receive confirmation by bacteriologic procedures.

Bile in High Intestinal Obstruction.—The results of experiments performed by Benedict and his associates on dogs suggest that, when obstruction of the intestine is so high that no bile can be reabsorbed, benefit is derived from administration of bile below the obstruction. In obstruction well below the bile papilla, in which some reabsorption of bile is possible, there is probably no special advantage to be derived from the exhibition of bile. While these experiments would appear to indicate that a lack of bile in the segment below the obstruction is not a factor of fundamental importance in determining the fatal issue in obstructed dogs, they do not preclude the possibility of benefit being derived from the use of bile in the lower bowel in the human subject suffering from paralytic distention. The composition of bile with respect to the bile salts and the cholesterol content is apparently not altered by intestinal obstruction. When the chloride and water balance is maintained, the length of survival of an obstructed dog seems to depend almost entirely on (1) the exact level of the obstruction below the bile papilla and (2) the fat reserve.

Plastic Reconstruction of Common Bile Duct.—Schrager and his associates describe a new method for the plastic reconstruction of the common bile duct. A viable tube from 1 to 2 inches (2.5 to 5 cm.) long is made from a flap of pyloric mucosa. This tube may be anastomosed either to the gallbladder or to a biliary duct. The gastric orifice of the tube is constructed to prevent regurgitation. The authors have performed the operation successfully in a number of dogs without postoperative complications appearing within a period of from two to three months.

Experimental Spinal Anesthesia.—Observations made by Ferguson and North on dogs anesthetized by the subarachnoid injection of procaine hydrochloride at varying levels permit the following conclusions: 1. Accompanying a typical anesthesia, there is a fall in blood pressure averaging 56 per cent, a slowing of the pulse rate, and a diminution in the respiratory movements of the thorax. 2. The fall in blood pressure cannot be explained on the basis of a splanchnic paralysis. Division of the splanchnic nerves produces only a slight alteration in the general blood pressure, and the typical fall of spinal anesthesia can be produced in animals with both splanchnic nerves completely severed. The entire vasomotor system participates in a vasodilatation, and the degree of blood pressure depression is in direct ratio to the number of white rami anesthetized. 3. The fall in blood pressure may be greatly ameliorated by the vasoconstrictor effect of preliminary medication with ephedrine. 4. The retardation of pulse rate is probably due to an interruption of impulses in the cardiac accelerator nerves. 5. Paralysis of motor fibers to the intercostal nerves seems to account for the depression of thoracic respiratory excursions. 6. Complete suppression of respiration occurs when procaine hydrochloride reaches the cervical portion of the cord and the medulla in sufficient concentration to paralyze the phrenic nerves or the respiratory center itself.

Varicose Vein Solutions.—According to Kilbourne and his associates, mercuric chloride and red mercuric iodide in the injection treatment of varicose veins have been fatally toxic in three cases. Metaphen is less toxic and is not likely to cause a slough. Experiments on rabbits did not indicate serious danger from toxicity in other solutions tested. Sugar derivatives, and sodium chloride, are nontoxic and relatively painless. Their use has been associated with an incidence of deaths from infection and embolism not found with quinine-urethane. Unlike quinine-urethane, they are not self-sterilizing or bactericidal. Since they are easily contaminated, they should be handled with extraordinary care in technic to prevent infection. The sloughs which they make when injected out of the vein are less serious than the salicylate and quinine sloughs. Sodium salicylate is efficient as a sclerosing agent. It is bactericidal to Staphylococcus aureus only in the strong solutions. It may cause a painful cramp after injection, and the sloughs which it makes are more serious than those following dextrose and sodium chloride. Lithium salicylate avoids the pain of sodium salicylate but is slightly more toxic and is said not to keep well in solution. Sodium morrhuate is not a toxic solution, and if injected out of the vein, the sloughs which it makes are not so serious as the salicylate and quinine sloughs. It is not bactericidal or self-sterilizing. Quinine-urethane is highly efficient as a sclerosing agent and, even when diluted, is bactericidal to Staphylococcus aureus. It has a perfect mortality record, possibly because of its bactericidal action in preventing phlebitis and embolism. It may be slightly toxic to occasional patients and when injected out of the vein does not give the warning of pain given by the other solutions. It causes no pain at the time of injection, and if the leg is kept bandaged, the occasional pain the next day is usually prevented. Because of its perfect mortality record, the authors regard it in expert hands the solution of choice—except in small-superficial thin walled veins, provided of course it is used by those sufficiently experienced not to allow extravascular escape.

Primary Benign Tumors of Ureter.—Melicow and Findlay report in detail a case of primary benign ureteral neoplasm accompanied by a stricture of the ureter, ureteral and renal calculi, and marked dilatation and infection of the kidney pelvis and ureter. This combination of lesions has never before been reported. The literature is carefully reviewed. From their study of these cases, the authors conclude that primary benign ureteral tumors are rare lesions which are infrequently diagnosed. The treatment that is safest for the patient and offers him the best chance for a cure is primary nephro-ureterectomy.

Infections and Degenerations of Uterine Cervix.—Mayo presents evidence that the difference in death rate between total abdominal hysterectomy and subtotal abdominal hysterectomy is slight, if any, and that the higher death rate usually attributed to total abdominal hysterectomy is probably due to the selection of graver surgical risks rather than to differences due to operative technic. It is also claimed that more patients would die from the complete operation than would die from carcinoma developing in the remaining stump of the cervix. If surgeons who fear to perform total hysterectomy accept the responsibility for the future life and health of the patient and feel that the cervix is a potential source of carcinoma and often a focus of infection, it is suggested that they perform subtotal hysterectomy and follow this procedure ten or twelve days later by some method of removal of the cervix, of enucleation of the canal, or of destruction of the cervical canal by cautery. Occasionally this procedure brings to light an otherwise hidden early carcinoma. The procedure would not increase the mortality and would accomplish all that is desired. The patient who has undergone subtotal hysterectomy only should be advised to return from time to time for observation. In some cases it may be advisable to use the actual cautery on the cervical stump, or prophylactic douches, in an attempt to clear up infection. The views given were reestablished in the author's mind because of a recent review of cases at the Mayo Clinic, which brought to light that, between January, 1910, and July, 1930, ninety-nine patients who had undergone subtotal hysterectomy there or elsewhere had presented themselves later with carcinoma of the remaining stump. In 55 per cent of these, carcinoma had developed three years or more after subtotal hysterectomy, and the longest interval was twenty-nine years.

Acute Suppurative Pleurisy in Children.—From a study of 123 cases of acute suppurative pleurisy in children and of comparative data, Cohen believes that the open method of drainage preceded by repeated aspiration is the choice method of treatment. Simple intercostal incision with open drainage is the preferred procedure in the very sick and in infants; rib resection for all other children. Local infiltration with procaine hydrochloride should be used whenever possible and can be used in most cases. The complications of empyema, and not the disease itself, seem to play the greater part as contributors to the mortality from this disease. Acute otitis media, in some cases complicated by acute mastoiditis, was the most frequent complication. Proper prophylactic care of the nasopharynx is recommended. Diligent after-care, next to the operative method, is important in surgically treating this disease. The value of operative methods must be measured not by the resulting mortality alone but by their ability to shorten the period of convalescence, to diminish the incidence of secondary operations, and to prevent chronicity.

Maggot Treatment of Chronic Osteomyelitis. — In a series of 100 cases including infections resulting from fractures, tuberculous and pyogenic chronic osteomyelitis, and an infected stump following repeated amputations, Livingston has had 95 per cent of cures with the maggot treatment. The success of this treatment does not alone depend on the scavenger activities of maggots. A series of experiments to be reported at an early date would seem to show that some additional agent is developed within the wound which is sufficiently powerful to overcome infection and permit the normal hydrogen ion concentration balance to be established. This agent is believed to be a bacteriophage.

Mixed Tumor of Lacrimal Gland.—According to Sykes and Williams, tumors of the lacrimal gland are comparatively rare. The most common type is that of the mixed tumor. These tumors are potentially malignant and should be considered as such. The exact origin of the mixed tumor is not known, but it is thought to be derived from epithelial structures. The authors report a case of a mixed tumor of the left lacrimal gland, verified by microscopic examination.

Submucous Resection in Children. — Windham believes that submucous resection affords the best relief for a blocked nasal passage and that the procedure should not be followed by deformity if the proper precautions are observed. The ultimate effects of submucous resection in relieving nasal obstruction in children cannot be denied. Bias should be laid aside and surgical procedures selected to meet the exigencies of the case under consideration. There is a positive need for relief of children under the age of puberty who are suffering from nasal obstruction. Mouth breathing can never supplant nasal respiration; the part must do what it is intended for. No one not skilled to do the classic operation in adults should operate on children, as bad results will follow. The operation of submucous resection is not entirely successful, unless interference with drainage and ventilation of the sinuses has been remedied; but, when indicated and properly performed, the results are gratifying. The best guard against sinusitis and sinus operations is perfect drainage at a time when sinusitis can be prevented, which is attained only by a physiologically perfect nose.

Spontaneous Subarachnoid Hemorrhage. — Blackford states that spontaneous subarachnoid hemorrhage is apparently not a rarity although it has been neglected in American literature until recent years. It may occur at any age and is relatively common in young people. There are many possible causes for its occurrence, but a congenital cerebral vascular anomaly is probably responsible for more cases than any other single cause. Its onset is usually abrupt. The symptoms are those of a combination of mechanical pressure and meningeal irritation. A homogeneously bloody spinal fluid is always present. The immediate prognosis is grave and recurrences are not uncommon. The treatment consists of controlling the intracranial pressure and removing the irritating fluid when necessary. Of four cases presented by the author, a definite etiologic diagnosis of a congenital vascular anomaly was established by necropsy in the only fatal case. This diagnosis seems most probable in two others, and in the remaining one it may well have been the cause. All four cases were characterized by the abrupt onset of coma in otherwise healthy persons, three of whom were under 30. Headache, mental confusion and signs of meningeal irritation occurred in all those surviving. In three instances, evidence of increased intracranial pressure was obtained. Two of the patients suffered from respiratory failure presumably due to a medullary compression. All the spinal fluids were homogeneously bloody, and fever was a constant observation. Leukocytosis was present in the three cases in which a white count was done, and albuminuria, transient in character, was demonstrated in the two cases in which a urinalysis was performed within twenty-four hours after onset. There was no glycosuria in this series. Evidence of syphilis was lacking in all four. Therapeutic lumbar puncture apparently gave definite relief from meningeal symptoms in the three cases in which it was used. Caffeine seemed to relieve the respiratory failure of the fatal case. The three survivors are at present without signs or symptoms attributable to their illness.

Transurethral Resection of Prostate.—Stirling considers that in median bars, contracture and other forms of minor obstruction of the vesical outlet, transurethral resection is the method of choice. In hyperplasia of the lateral or median lobes, the obstruction can be corrected in grade I, II and III, but should not be used in grade IV or the highly vascular type of obstruction or in old, feeble subjects. In the presence of complications, such as diverticula or stone, resection may be followed by litholapaxy or excision of the diverticulum. Hemorrhage can and must be adequately controlled by using the fulgurating or spark-gap current, thus eliminating the principal hazard connected with this procedure. The mortality has been greatly lessened, the morbidity decreased and the average stay in the hospital reduced to days instead of weeks as formerly. Transurethral prostatic resection is a highly technical procedure and meets all the requirements for this type of work. By treating the patients earlier, one will greatly reduce or obviate cardiovascular, renal and the systemic derangements following massive retention. Preliminary cystoscopy, orienting the type and character of the obstruction, is necessary. Resection is a supplement to and not a substitute for prostatectomy, each having definite, clear-cut indications.

"Angina Capitis."—Michaelson presents a summary of the chief known facts of referred visceral pain, physiologic, clinical and experimental. On the basis of a study of the activity and innervation of the ciliary muscle, of the clinical features of ocular headache, and of an experimental relationship between the skin and the ciliary muscle, he concludes that there is a sufficient concurrence between the two sets of facts to justify the suggestion that the mechanism which underlies ciliary headache is analogous to that which gives rise to referred visceral pain in other parts of the body, more particularly that ciliary headache arises from ciliary dysfunction in the same way in which angina pectoris arises from cardiac dysfunction.

*Carbon Dioxide in Prophylaxis and Cure of Postanesthetic Respiratory Complications. J. R. Mackenzie.—p. 561.

Oleothorax.—Munro considers that oleothorax is the treatment of choice in suitable cases of tuberculous empyema and that it proves an alternative of the more drastic procedure of thoracoplasty in certain conditions complicating a spontaneous or artificial pneumothorax. The technic is simple and speedy with a Dieulafoy two-way syringe and flexible metal attachments. Olive oil is to be preferred to liquid petrolatum because the latter is a pleural irritant. Because of its irritant properties, aromatized oil should be added to the oil only when an effusion is being replaced, and then in graduated strengths. Discretion regarding the oil used makes complications negligible. Before a case can be considered suitable for treatment, it seems to demand requirements similar to those governing artificial pneumothorax therapy. Thus the condition of the contralateral lung and of other tissues regarding tuberculous involvement has to be considered before instituting treatment. The ideal cases are naturally few, and the author was occasionally tempted to overlook quiescent foci in other organs for the sake of determining the more immediate results of this treatment. The outlook for the more advanced case of tuberculosis is so hopeless that the patient's gratification at knowing that some treatment is being attempted seems to jusify such liberties with oleothorax.

Carbon Dioxide in Postanesthetic Respiratory Complications.—Mackenzie reports his experiences in 5,000 cases in which carbon dioxide was administered in combination with general anesthesia. Among the advantages that accrue to the surgical patient, three stand out prominently: (1) the prophylactic action of carbon dioxide against the onset of respiratory complications, irrespective of the anesthetic agent; (2) the protection afforded to patients who come up for operation with concomitant respiratory disability, and (3) the curative action of carbon dioxide when postanesthetic respiratory complications have occurred. For purposes of observation, the cases are arranged in four groups. In the first and largest group, carbon dioxide to the extent that appeared advantageous to the patient was administered in the operating room, during the induction, the maintenance and the recovery stages of gas, oxygen and ether anesthesia. In the second group, carbon dioxide was used in the induction and recovery stages of deep ether anesthesia. In the third group, carbon dioxide was used as a prophylactic against respiratory complications during the recovery stage of anesthesia in the operating room and in the ward after the operation. In the fourth group, carbon dioxide was administered as a therapeutic agent in cases of postanesthetic respiratory complications. The tendency has been for the first three groups to merge into one, and recently, as far as it has been possible, the patients have had carbon dioxide during the induction of and recovery from anesthesia, in the operating room and in the ward, at regular intervals throughout the first twenty-four to thirty-six hours after the operation. The author has evolved the following technic of administration: 1. Pulmonary ventilation is controlled and regulated to the normal during the induction and maintenance of anesthesia. 2. During the closing stages of the operation, hyperventilation and deetherization is carried out until the patient leaves the operating room. 3. In the ward the administration consists of the inhalation of carbon dioxide and oxygen for five-minute periods. These periods are continued at intervals of from four to six hours throughout the first twenty-four to thirty-six hours after the operation. 4. This periodic administration is continued if there is any evidence of respiratory complications. The percentage of carbon dioxide, the duration of the period, and the frequency of administration should be regulated according to the toleration of the individual patient. The apparatus used in the ward consists of a small platform on casters to carry one cylinder of carbon dioxide and one cylinder of oxygen, with a central standard to carry a sight feed bottle. It has proved eminently simple and satisfactory. The freedom from pain in abdominal wounds during hyperventilation with carbon dioxide as compared with the pain and distress which the patient endures in voluntary deep breathing is a marked feature of the administration.

Chronic Nontuberculous Infection of Lungs in Children.—Young believes that in chronic nontuberculous infection of the lungs in children the child should be removed, if possible, from other members of the family with chronic coughs; it is probable that reinfection does take place when once the ground has been prepared. In cases in which this is impossible, an open-air school will probably produce marked benefit. Extra rest should be insisted on; the child should have long nights and should lie down for a couple of hours in the afternoon, preferably in the open air. Any definite sepsis or obstruction in the upper air passages must be dealt with. Breathing exercises are of great value; they expand the bases of the lungs and tend to permit efficient drainage. In the absence of real sunlight, artificial sunlight is usually the main method of attack for increasing the general resistance. The diet should be liberal and contain considerable quantities of vitamins. Cod liver oil and malt should always be given, and plenty of fresh fruit and vegetables. The author has found the use of dextrose to be valuable. He has been trying these children on vaccines for some time, and in certain cases there has been a benefit; on the whole, however, the results have been disappointing. When the disease has reached a more advanced stage and sputum is a prominent feature, postural drainage is beneficial. Drainage by means of a bronchoscope is only palliative, and it is impracticable to get this done often enough to be of any great use. Collapsing the lung by means of an artificial pneumothorax would be valuable if practicable, but in nearly every case adhesions prevent an adequate collapse. Evulsion of the phrenic nerve seems to be the most reasonable form of treatment in more advanced cases. Lobectomy of the affected lobe is such a severe operation that it is hardly feasible at present. Thoracoplasty in children is not satisfactory; the deformity of the chest is very severe, and the results do not seem to justify the risk. Expectorants and inhalants are disappointing; they may be of some symptomatic value in relieving the cough and making the sputum, if it has become offensive, less so. The use of the creosote chamber is probably the most efficient method, as by this means any stagnant secretions are generally brought up. The severity of the cough, however, in a chamber of this kind frightens the child so badly that it is hardly practicable.

Significance and Origin of Lactic Acid in Gastric Contents.—Murray and Robertson report that an investigation of test meals from fifty subjects, pathologic and normal, showed the presence of lactic acid in 74 per cent. While occurring more frequently in cases of hyposecretion, it may be present even in hypersecretion. The presence of lactic acid had apparently no clinical significance. The production of lactic acid was almost certainly due to the action of Bacillus acidilactici, which was found to be present in the perfectly normal stomach.

Clinicopathologic Study of Carcinoma of Stomach, Using Large Microscopic Sections and Dissecting Lymphatic Spread. E. B. Benedict.—p. 263.

Complement Fixation in Meningococcal Infections.—Cookson emphasizes the fact that although the complement fixation method appears to offer further confirmation in cases diagnosed or thought to be meningococcal infections, in common with all serologic tests, it must not be considered apart from the clinical and other observations in each individual case. In the author's opinion it in no way displaces the significance of a polymorphonuclear leukocyte exudate when such is present, or the value of the estimation of chlorides when a lymphocytic preponderance occurs, for the chloride figure is rarely very low in meningococcal infections in his experience. In cases in which no alteration in the spinal fluid can be observed, the examination of the blood serum by complement fixation tests may give a clue to the condition. In difficult cases, if one or more of the triad (1) polymorphonuclear leukocytes in spinal fluid, (2) not a very low chloride content, (3) positive fixation test should be found, the author considers that the clinician should treat the patient for a meningococcal infection.

Guy's Hospital Gazette, London

46: 121-136 (April 2) 1932

*Meningitis and Meningism. J. A. Ryle.—p. 123.

Vincent's Infection. A. Bulleid.—p. 127.

Meningitis and Meningism.—Ryle believes that, while they are specific of meningeal irritation, the symptoms of meningism are nevertheless not specific of any one type or cause of irritation. This is true of all well defined symptoms. They constantly specify a type or mode of physiologic disturbance, but they do not in themselves indicate the particular cause of the disturbance. For a full diagnosis other clues must be sought in the age and the general condition of the patient, in the history, and in associated symptoms and signs. There are four main groups of cases in which meningism may be observed: (1) acute pyogenic meningitis (meningococcic, pneumococcic, streptococcic); (2) subacute meningitis complicating general tuberculosis, poliomyelitis or activated syphilis; (3) the aseptic meningitis of subarachnoid hemorrhage, and (4) the meningeal irritation or aseptic meningitis of pneumonia and otitis media in children. With ordinary clinical care it should be possible to place a case in one of these four groups, and often enough to give a correct opinion. With the aid of the lumbar puncture needle, an accurate diagnosis can generally be established.

Note on Treatment of Functional Aphonia. C. MacMahon.—p. 243.

Malignant Disease of Hypopharynx.—According to von Eicken, malignant tumors of the hypopharynx may be divided into two groups. The first group includes tumors arising from the lateral walls of the larynx, the outer surface of the epiglottis, the pharyngo-epiglottic fold and the plica aryepiglottica. The tumors of the second group take origin from the sinus pyriformis and the lowest parts of the hypopharynx. The tumors of the first group develop more slowly and form metastases later than do those of the second group, which are of rapid growth and show early metastasis in the regional lymph nodes. Recently the French school has proposed a division of these tumors into two groups, which can be distinguished by their microscopic appearances. The first is the epidermoid or cutaneous type, which is characterized by the presence of typical epithelial pearls and prickle cells. The second is the anepidermoid or mucous type, and it shows the so-called Hollundermarkzellen, which are large polyhedral cells with so transparent a protoplasm as to produce a vacuolated appearance. True epithelial pearls are not present, but the laminated arrangement of the so-called onion bodies, which are a constant feature of this type of tumor, may cause confusion; however, a distinction is readily made when it is observed that well marked nuclei are present. Both these types are found relatively often in the hypopharynx, but the mucous type is the more frequent.

Practical Points in Diagnosis and Routine Treatment of Pulmonary Tuberculosis. P. W. Edwards.—p. 709.

*Pecten: Pecten Band: Pectenosis and Pectenotomy. A. L. Abel.—p. 714.

*Active Principle in Hog's Stomach Effective in Pernicious Anemia. J. F. Wilkinson and L. Klein.—p. 719.

Diagnosis of Diseases of Hip Joint. J. F. Brailsford.—p. 721.

The Pecten Band.—Abel states that the "pecten" is the name given by Stroud in 1896 to approximately the middle third of the anal canal. In a normal subject this has a glistening appearance, is quite smooth, and is almost entirely devoid of sweat glands. Above it is bounded by the wavy dentate or pectinate line caused by the anal papillae, and below by Hilton's white line. The pecten marks the union of the proctodeum and the hind gut. The part below the pecten is formed by an ectodermal depression named the proctodeum; the part above this line is formed from the hind gut. The pecten band is a fibrous deposit that takes the form of a circular band varying in thickness and density, completely surrounding the lower part of the anal canal, and situated between the mucous membrane of the pecten and the external sphincter muscle. In well marked instances the band of fibrous tissue can be distinctly felt and gives an impression to the examining finger such as would be obtained if a rubber umbrella ring had been inserted beneath the skin at the anal margin. The pecten band does not exist in the healthy anal canal. It is purely pathologic in origin. Passive congestion in the region of the pecten may be brought about by a number of factors. Probably the commonest is the varicosities of the superior hemorrhoidal veins. Constipation alone without the presence of hemorrhoids has an exactly similar effect, as has also spasm of the sphincter muscles. With the passage of months and years, the pecten band becomes more and more dense and prevents the proper relaxation of the sphincters. There is then difficulty in obtaining complete emptying of the rectum, the size of the caliber of the feces is diminished, and the lower half of the anal canal tends to be held immobile, while the elevating effect of the pubococcygeal part of the levator ani muscle has the effect of pulling the internal away from the external sphincter, thereby causing sometimes as much as an inch of separation between the two sphincters and still further increasing the difficulty in obtaining complete emptying of the rectum during defecation. The tighter the anal aperture becomes, the greater the straining at stool; hence any hemorrhoidal condition tends to be aggravated, and if hemorrhoids become prolapsed through the anal orifice they are apt to become strangulated by the nonyielding pecten band. As a result of this deposit of fibrous tissue in the submucosa of the pecten, the mucous membrane of this region, instead of being freely movable over the subjacent tissues, becomes anchored to it and poorly nourished with blood. This renders it much more easily damaged than in a normal subject. It is uncommon to find a fissure in a patient without a preexisting pecten band. If the anus is everted in a patient suffering from fissure, definite white strands of fibrous tissue can be discerned running circularly around the anal canal at the bottom of the fissure; and if a portion of this tissue is taken for microscopic section it will be found to consist of fibrous tissue only. The mucous membrane of the rectum frequently becomes unhealthy in patients with long standing pectenosis; secretion of normal rectal mucus is apt to become excessive, and the patient suffers from pruritus ani. When no other pathologic condition exists in the rectum, pruritus of these patients may be cured by performing the operation of pectenotomy, the technic of which the author describes in detail.

Hog's Stomach in Pernicious Anemia.—Wilkinson and Klein have been unable to obtain stomach extracts that are hematopoietically active for the treatment of pernicious anemia by the usual methods which, when applied to liver, yield active extracts. They describe a method of obtaining active stomach extracts which involves the subjection of stomach tissue to high pressure in a special apparatus. Experiments on the fractionation of this active extract are described; it was found that the use of alcohol readily separates a precipitate which is active in the treatment of pernicious anemia while, on the other hand, the filtrate is inactive. Further experiments on the concentration of this active fraction are in progress. Some evidence showing that the active principle in hog's stomach is not identical with that present in liver is discussed. It is considered that these experiments support the clinically suggested view that the active principle in hog's stomach effective in perinicious anemia is of an enzyme-like nature. The suggestion is made that this "enzyme" acting on the proteins in a normal diet may produce a substance which is stored as the active principle in the liver until it is required for hematopoietic regeneration. For convenience the authors propose temporarily to term this substance in hog's stomach "haemopoietin."

Occult Tuberculosis of Tonsil in Relation to Tuberculous Cervical Adenitis.—Webster presents the results of an investigation regarding the incidence of tuberculosis in the tonsils of 132 children. Of eighty-six children exhibiting tuberculous cervical adenitis, forty, or 46.5 per cent, were shown to have tuberculous lesions in the tonsils. Among forty-six pairs of tonsils removed for simple hypertrophy or other cause apart from tuberculous cervical lymph nodes, no instance of tuberculosis of the tonsil was detected. The value of histologic diagnosis is discussed. Emphasis is laid on the fact that primary tuberculosis of the tonsil is seldom, if ever, apparent clinically. On the basis of the results of his investigation, the author concludes that tonsillectomy is clearly indicated in the treatment of tuberculous cervical adenitis.

Elusiveness of Tubercle Bacillus in Gross Lung Lesions.—Cumming and Foster stress the importance of frequently repeated microscopic and cultural examination of the sputum and, more particularly, of repeated animal experiment in many cases of pulmonary catarrh and fibrosis before one excludes, on bacteriologic grounds, the possibility of the lesion being tuberculous. As a routine, all sputums in which tubercle bacilli are not demonstrated microscopically in a direct smear after a careful fifteen minutes' search should be subjected to "concentration" by the following method: The sputum is digested in an alkaline medium, neutralized and centrifugated after the addition of two drops of egg white; smear preparations are made of the deposit and scum, if any. More than one tubercle bacillus must be demonstrated before the result is accepted as positive. Further, an attempt is made to isolate tubercle bacilli, generally on Dorset's egg medium, by direct cultural methods (after concentration by a method similar to the one described) from the sputum of every patient admitted. Guinea-pig inoculation is not used as a routine method unless, after culture has failed and repeated microscopic examinations of concentrated specimens have been negative, the result of clinical methods of investigation still leaves open the possibility that the lesion is tuberculous.

Pleural Effusion in Artificial Pneumothorax.—Ford believes that all pleural effusions complicating artificial pneumothorax are due to the breaking down of adhesions. He is led to this conclusion by the following facts: 1. Adhesions are extremely common; it is in only a small percentage of cases that an absolutely complete collapse is obtained. 2. Thoracoscopic examinations have shown that the size and strength of adhesions vary considerably. 3. Effusions occur most frequently at the commencement of the treatment; i. e., while the adhesions are being stretched. 4. A large majority of cases show marked improvement and a greater amount of collapse after the effusion occurs. 5. Cauterization of adhesions is almost invariably followed by an effusion.

Puerperal Creatinuria.—Eastman and Lee report that lactating puerperas excrete little urinary creatine during the first two or three days of the puerperium, but immediately thereafter a rapid increase in the creatine-creatinine ratio occurs so that on the sixth day it reaches levels which average about 0.6. Nonlactating puerperas, on the other hand, exhibit a very high creatine-creatinine ratio on the second day post partum, followed by a rapid decrease in the amount excreted, so that by the seventh or eighth day the urinary creatine in this group is usually reduced to a trace. Compound solution of iodine, in doses of 1 to 2.5 cc. daily, has no effect on the creatine excretion of the puerperium; the basic mechanism of puerperal creatinuria, therefore, differs from that seen in exophthalmic goiter, in which compound solution of iodine has been found to diminish the creatinuria. Puerperal creatinuria closely parallels mammary engorgement and seems to be related in some unknown way with the excessive distention of the mammary ducts with milk.

Escape of Iodized Oil into Utero-Ovarian Venous System in Hysterosalpingography.—Wong and his associates report four cases in which the injection of iodized poppyseed oil 40 per cent into the uterus during hysterosalpingography was followed by appearance of the oil in the utero-ovarian system. It is fortunate that the amount of oil escaping during a hysterosalpingography is usually too small to be of any clinical significance. Nevertheless this oil is able to kill an animal when it is given intravenously in sufficiently large doses. The authors were able to kill rabbits weighing from 1.5 to 2 Kg. by introducing 1 cc. of the drug intravenously. The possibility of this danger should be borne in mind, and care taken to avoid it. The authors are therefore in favor of carrying on the intra-uterine injection of iodized oil between seven and ten days after the cessation of the menstrual period and under the fluoroscope to avoid such an accident. Using this technic for the last three years, they have not encountered a single accident of this nature. They believe that injecting under sight is better than any arbitrary way of regulating the pressure, since the permeability of the endometrium varies greatly in different individuals. Practically speaking, this observation deserves serious consideration. If oil can make its way into the utero-ovarian venous system so easily during hysterosalpingography, it will be quite easy for air or any other gas used in Rubin's test to enter and lead to a disastrous result. In fact, two cases in which death followed insufflation of the fallopian tubes have been reported by Maench; other undesirable manifestations have been related by Aldridge and by Kern. The authors are beginning to doubt Rubin's statement "The method proposed by me should never result in mortality," since iodized poppy-seed oil 40 per cent escapes thus readily, as seen in their cases. For this reason a hysterosalpingogram used with the fluoroscope is to be preferred to Rubin's test.

Wassermann and Kahn Reactions of Human Milk.—In 140 nonsyphilitic cases, agreement of the blood and milk was found by the Wongs in 99.2 per cent of the Wassermann reactions and 94.8 per cent of the Kahn reactions. In eleven syphilitic cases from which the milk specimen was obtained by the tenth day post partum, agreement of the blood and milk existed in 50 per cent of the Wassermann reactions and 70 per cent of the Kahn reactions. On the basis of their observations, the authors conclude that the Wassermann and Kahn reactions of human milk are not sufficiently reliable to be used as an alternative to the blood Wessermann and Kahn tests.

Prostatectomy.—Marion discusses again the suprapubic route of prostatectomy in chronic prostatitis, which he recommended several years ago. He considers it preferable to the subpubic route in many cases as it avoids the danger of the interminable perineal fistulas that so often follow the latter method of operation. He thinks the operation indicated in the following types of chronic prostatitis: (1) lightly suppurating cases of slight importance from the anatomic point of view but resistant to all medical treatment, (2) cases presenting voluminous fistulized abscesses in the urethra, (3) cases accompanied by perineal fistula with periprostatitis, (4) cases presenting calculi, and (5) cases accompanied by hypertrophy of the prostate. The author thinks it advisable to confirm the indication for operation by urethrography. The technic of intervention in these cases, which differs a little according to the case, is described. In a number of cases the author has practiced a preoperative vaccination and he has never had any bad results in these cases, whereas in one of the cases in which he did not practice preoperative vaccination a general infection ensued. The author does not consider these interventions more dangerous than prostatectomy for hypertrophy and has experienced only two deaths among seventy-four interventions.

*Pleural and Pulmonary Primary Forms of Hodgkin's Disease. J. Bernard.—p. 286.

Various Technics in Roentgenologic Examination of Lungs.—Dioclès and Azoulay discuss the indications for the use of the various technics of roentgenologic examination of the lungs and the special merits of each method. Roentgenoscopy is useful in the location of large lesions and indispensable for execution of artificial pneumothorax, but it is deficient for diagnosis of many cases, especially miliary lesions. Whenever roentgenoscopy does not show anything but the clinical examination or anamnesis indicates something, a roentgenogram is indispensable. Roentgenography at a great distance usually suffices, but it should be supplemented more frequently than customary by profile and oblique negatives. The use of an antidiffuser is useful in cases of obesity, fibrothorax and large pleurogenous symphyses. When interpretation of simple roentgenograms is not possible, it is necessary to employ stereoroentgenography. This technic is useful in the course of artificial pneumothorax as it shows the shape of the stump and the location of adhesions and the presence of cavities in them, which may facilitate the operation of Jacobéus. It often permits location of foreign bodies or intrathoracic collections, which is of practical value from the point of view of surgical drainage at the most dependent point. It is indispensable in the study of the posterior mediastinum, whether one uses profile position, right anterior oblique position or left posterior oblique position. In these cases one can facilitate the reading of the negative by filling the esophagus with barium paste. It is equally indispensable for the diagnosis and location of cysts and tumors of the lungs and pleura; of hernia or eventration of the diaphragm from the point of view of location of the hernial orifice. Bronchial dilatation, simple or masked by pleurogenic symphysis of the mediastinum or of the large cavity, may sometimes be diagnosed by stereoroentgenography alone; when preceded by injection of iodized oil, positive diagnosis is possible. In cases of pleural or pulmonary suppuration, injection of iodized oil into the bronchi gives a particular negative aspect which is of great value. The direct injection of suppurating cavities, whether by puncture or by a fistulous orifice, is highly important. Despite the progress of technic it is impossible to solve all problems with roentgen rays and to give a precise diagnosis in all cases.

Pleural and Pulmonary Primary Forms of Hodgkin's Disease.—Bernard presents a comprehensive study of the symptoms of those pleural and pulmonary disturbances which exist as primary forms of Hodgkin's disease. Pleurisy as a primary form of Hodgkin's disease is relatively frequent, whereas a primary pulmonary localization of the disease is rare. The clinical aspects of primary pleural forms of lymphogranulomatosis are diverse. A rather frequent form is the one that has practically all the traits of serofibrinous pleurisy. In the presence of a serofibrinous pleurisy which cannot be otherwise accounted for, one should immediately think of Hodgkin's disease. The intensity of the dyspnea is the major element of the clinical picture. The unlimited production of fluid and its variegated cytologic picture are the essential characteristics of granulomatous pleurisy, but they are far from being constant. Whether it evolves slowly or rapidly, as a solitary manifestation or followed by other symptoms of the granulomatous complex, the pleurisy sooner or later becomes grave and terminates fatally. Any splenopleural or adenopleural syndrome should make the clinician think of Hodgkin's disease, especially in case of an adenopathy exhibiting the irregularity, indolence and total absence of softening and of tendency to suppuration, which is characteristic of the disease. The evolution of primary pulmonary forms of malignant granuloma manifests itself in symptoms that are rather common, so that for a long period there is usually nothing which permits their true nature to be suspected. Usually they assume the form of a chronic or subacute pneumopathy. The objective and subjective symptoms and the roentgenologic manifestations are discussed by the author, who finds none of them characteristic. In contrast to granulomatous pleurisy, the pneumopathies are seldom grave in themselves; but sooner or later the disease becomes generalized and the patient dies of cachexia or a complication. Hemoptysic, pseudomiliary, bronchopneumonic and mediastinopulmonary forms are mentioned; also the pleuropulmonary form. The diagnosis of pleurisies and pneumopathies that exist as primary forms of Hodgkin's disease is difficult. The former is most often confused with pleural tuberculosis and the latter, if of the silent type, is often mistaken for tuberculosis; or, if of the more characteristic type, it is mistaken for cancer of the lung. Roentgenologic visualization of a tracheobronchial adenopathy speaks against tuberculosis in adults. Histologic examination of a peripheral lymph node should be practiced when possible, as it aids in diagnosis. In its absence, diagnosis is often impossible.

Practice of Surgical Interventions Under Local Anesthesia. H. V. de Paula.—p. 238.

Azotemia in Tetanus.—Vaccarezza and his co-workers observed an increase of the blood urea in twenty out of twenty-four patients with tetanus. In some cases the hyperazotemia reached high figures and was accompanied by lethal uremic manifestations. The determination of blood urea has a considerable prognostic significance. One should not predict a cure during the first two weeks of the illness without having determined the blood urea. The treatment of tetanus should always envisage the existing danger of uremia, so that it may be prevented and combated as far as possible. The pathogenesis of uremia in tetanus is complex. There is a functional or anatomic retention and above all an excessive production of urea due to an increase in tissue proteolysis. Tetanus is dangerous not only because of its paroxysms and contractions and the possibility of bronchopulmonary complications but also because of the disturbance of the azotemic equilibrium and the sugar regulation. Its toxic action is not limited to the nervous centers but extends directly or indirectly to other systems and to the organs influencing metabolism.

Congo Red as Diagnostic Measure in Amyloidosis.—Vivoli reports and discusses investigation of five cases of amyloidosis to support his statement that congo red is a valuable diagnostic measure in amyloidosis. His investigations show that (1) it is possible to obtain a vital staining of amyloid with congo red, without harm to the patient; (2) a retention of from 40 to 100 per cent of the dye one hour after injection speaks in favor of the probability of amyloidosis. Normally there is a retention of from 11 to 29 per cent of the coloring matter; the retention takes place chiefly in the liver and the kidneys. Its elimination commences about thirty minutes after injection and lasts from eight to ten days. In certain pathologic conditions such as syphilitic nephrosis and the beginning stage of glomerular amyloidosis the kidneys eliminate more rapidly and in greater amounts, so that the dye is quickly eliminated by the kidneys without being fixed. In advanced amyloidosis the dye disappears from the blood serum but cannot be found in the urine. In a case of this type in which slight traces of dye were found in the serum and the urine after the fourth test, the author attributes this to saturation of the amyloid substance by the congo red and elimination of the excess by the kidneys. In one case, necropsy three months after the last test revealed such a large quantity of fixed dye that it gave the impression that the injection had been performed several hours before death; no dye had appeared in the urine in the interval. From these considerations, the author thinks that the vital coloration of the amyloid tissue may last as long as the pathologic process itself.

Destructive Action of Iodine on Acid Resistance of Tubercle Bacillus. S. Marbais.—p. 377.
Pernicious Anemia and Tetany. M. Geraldy.—p. 378.
Colloidal Mercury Sulphide. Gennerich.—p. 378.

Phosphate and Calcium Under Influence of Viosterol.—Heubner observed that large doses of viosterol (for each kilogram of body weight of the animal from 5,000 to 50,000 times the antirachitic rat unit) effect in rabbits and cats after a temporary slight reduction a considerable increase of the inorganic phosphate content of the blood. This increase is best noticeable two days after a single oral administration. The elimination of calcium in rabbits and dogs is not noticeably influenced by administration of large doses of viosterol. However, after a certain time there is a more active participation in the elimination on the part of the kidney, for at times the freshly voided urine contains insoluble salts in suspension. The organs of rabbits that have been treated with large doses of viosterol do not show noticeable changes in the calcium content. Only in those animals in which anatomic examination revealed processes of calcification in the organs were deviations from the normal calcium content noticeable.

*Chronic Stenosis of Duodenum Due to Perivisceritis. M. Agrifoglio.—p. 1.
Large Tumor of Carotid Gland: Removal After Resection of the Jugulocarotid Bundle of Vessels and of the Vagus. C. Trinchera.—p. 52.
*Dermatitis and Precancerous Lesions from Tar in Man. G. Bettazzi.—p. 69.

Chronic Stenosis of Duodenum Due to Perivisceritis.—Agrifoglio states that essential periduodenitis originates through the portal system, being due to transitory inflammation of the adjacent organs (gallbladder, stomach, pancreas) or to the remote viscera (appendix) through the possible intermediary of a lymphangitis or to permanent peritoneal lesions on an old and transitory infection of the gallbladder, pancreas and appendix. Some believe that the perivisceral adhesions are occasioned by general infections, e. g., tuberculosis and syphilis, but the etiology of perivisceritis still remains uncertain. Factors tending to compress and displace the duodenum are (1) insufficient development of the base of the thorax, (2) lumbar lordosis, (3) relaxation of the abdominal wall, and (4) exaggerated mobility of the cecum or extreme length of the mesentery and mesocolon. The facility with which small bands of adhesions cause stenosis is explained by the position of the duodenum, which predisposes it to compression between the spine and the root of the mesentery. Clinical and roentgenologic symptoms differentiate compression due to the superior mesenteric artery from stenosis due to essential perivisceritis: clinically there will be general disturbances and pains, nausea and vomiting occurring in the true crises. Roentgenologically, compression by the superior mesenteric artery in the erect position shows a distinct arrest of the barium on the median line or a little to the right of it, at the point where the mesenteric pedicle passes in front of the duodenum with marked distention of the third portion and the lower angle of the duodenum. Stenosis of the duodenum due to perivisceritis following gastroduodenal ulcer is best determined by roentgen examination, which will show signs caused by the rigidity of the intestinal wall, wherever adherent, and atony of the segment concerned. Pain during palpation is an important symptom, especially when produced during the attempt to separate the viscera, and is all the more confirmative if it accompanies difficult or impossible dissociation of the suspected viscera. Medical treatment advised for minor obstructions of the duodenum consists in (1) sustaining the abdominal wall by means of a corset, (2) massaging and exercising the abdominal muscles, (3) dorsal decubitus on an inclined plane, holding the head low, and (4) resting after eating. Two generally used operations for periduodenitis are (1) liberation of the duodenum from adhesions, which permit it to reassume its normal form and size, and (2) operation to determine a good evacuation of the gastroduodenal segment situated above the obstacle. In periduodenitis due to ulcer, transmesocolic gastro-enterostomy with section of the adhesions is recommended.

Dermatitis and Precancerous Lesions from Tar in Man.—Bettazzi demonstrates histologically that the action of tar on human skin may cause either atrophy or epidermal hyperplasia. Since tar may cause atrophy of the papilla and of the hair until it disappears, it is natural that tar should act in the same way on the skin. The process of hyperplasia which generally accompanies alterations of the skin is explained by the irritative and proliferative action of the tar on the epidermal epithelium. The principal alteration of the skin, namely, lymphocyte and plasma cell infiltration, can be attributed to a true action of the tar. The author found in the skin of patients the presence of tar granules between the corneal layers in the zone of hyperkeratosis, in the dilated infundibula of the atrophied hair follicles, between the connective fibers of the superficial skin. He found no dermo-epidermal lesions of the exudative type with the presence of polymorphonuclear leukocytes, nor regressive processes habitually occurring in acute infections (pyodermatitis, acne suppurata, folliculitis). Concomitant alterations of the dermal connective tissue consist in the swelling of connective tissue bundles, disappearance of the characteristic fibrillations and alterations of staining affinity. The alterations are especially observed in zones of prominent proliferative activity of the epidermis, which consists in multiple deep epithelial digitations fusing into the derma, in epithelial layers or nests tending to form corneal pearls. The dermal lesions described prepare a basis particularly adapted to the invasion of the epithelial proliferation and it is also probable that in a ground so prepared the epithelial vegetation can easily acquire the morphologic alterations, the atypical characteristics true of cancer. The oncogenous action of tar in man is explained by a chronic irritation of the tissues by which the workmen in continual contact with the tar acquire microscopic and histologic lesions of the skin (chronic dermatitis which can turn to cancer). Of the number of workmen exposed to the action of the tar and its derivatives, only a few contract dermatitis and fewer still cancer. The patients can carry for a long time with impunity the epithelial neoplasms due to tar, demonstrating a relative biologic mildness. During this time they can be cured with opportune surgical aid, but local recurrences and malignant transformations of other cutaneous lesions are possible. The neoplasms are neoformations which, although having the morphologic characteristics of cancer, are differentiated from them clinically by an extremely slow course, by the lack of metastases, and by the complete absence of phenomena reacting on the general economy of the organism; however, in the course of time they can acquire all the biologic characteristics leading to death through metastases and cachexia.

*Rare Seat of Location of Echinococcus Cysts. A. Cioffi.—p. 254.

Echinococcus Cysts.—Cioffi explains the presence of echinococcus cysts in the bladder by embryos which, after having overcome the resistance of the porta and the pulmonary capillaries, constituting two filters of the portal and general circulation in the capillary reticulum of both the liver and the lungs, remain in the circulation and are arrested at some point of the organism, especially where the circulation is terminal. The parasites in the liver and lungs produce germinating cysts, while those that pass through the barrier of the pulmonary capillaries are smaller and produce acephalocysts. Contrary to what happens in the case of blood vessels which are gradually obliterated by endarteritis and endophlebitis, mucous canals included in the cystic walls do not tend to obliterate themselves. Despite their flattening, they remain permeable until compressed by the parasite, because their epithelium prevents fusing of their walls. This explains the elimination of hydatid detritus by the large excretory tubes (bronchi, bile duct and ureter).

Frequency of Tuberculous Infection Among School Children of Pécs (Hungary). L. von Dobszay and G. Petrányi.—p. 88.
*Favorable Outcome of General and Pulmonary Tuberculosis with High Fever During Childhood. G. Paschlau.—p. 94.
Pseudotetanus Escherich an Encephalitis? Maria Niermann.—p. 108.

Esophageal Spasm in Children.—Sudhues reviews the literature on esophageal spasm in children and then reports four new cases, in two of which there was a constitutional inferiority. She is convinced that careful examination, particularly with roentgen rays, will reveal that a spasm of the esophagus is frequently the cause of vomiting. She differentiates between primary and secondary spasms. The secondary spasms may occur in normal children following an injury or an inflammation of the esophagus. However, the primary spasm is probably due to a congenital inferiority of the sympathetic nervous system; namely, to a disturbance in the vagus or in the intramuscular plexus of the esophagus. The primary spasm is in nearly all cases in the lower third of the esophagus. A satisfactory explanation for this localization has not been found as yet. It has also been observed that the primary spasms are more frequent in boys than in girls. A group of cardiospasms with dilatation of the esophagus that occurs during the first year of life is explained as resulting from the abolition of the opening reflex of the cardia, which in turn is due to an injury of the vagus. This theory of pathogenesis is based on studies by Ylppö, Tamiya and Rieder.

Favorable Outcome of General and Pulmonary Tuberculosis with High Fever During Childhood.—Paschlau points out that among the patients in children's hospitals one occasionally sees children with new severe tuberculosis, with a poor general condition and with high fever, for whom the prognosis is apparently unfavorable. With surprise one notices in a number of these children that the high fever, which has persisted for several months, gradually subsides and that severe disseminated processes and focal or infiltrative pulmonary processes gradually regress and finally end in recovery. The author reports the case of a girl, aged 2½, in whom there was high fever and a miliary tuberculous dissemination with some typhoid-like symptoms. A second patient was a girl, aged 2, who had a subacute miliary tuberculosis. During the beginning stage the pulmonary symptoms predominated, and later numerous metastases developed in the bone system. He reports the cure of a nursling who had chronic torpid miliary tuberculosis with intercurrent epituberculosis of the lung. The fourth patient was a girl, aged 11, with pulmonary infiltration and high fever that lasted four months. The girl recovered. In regard to the treatment of hematogenic miliary tuberculosis, there is little to be done. He warns against irritation therapy in any form, ray therapy, and the injection of tuberculin or of nonspecific protein.

Causal Significance of Gastric Juice and of Hunger in Gastritis.—Puhl reports his observations during simulated feeding of esophagostomized dogs. He employed the technic of Pavlov and Silbermann, who produced gastric and duodenal ulcers by simulated feeding. The author is convinced that the causal factor of the degenerative processes resulting from the experiment is the hypersecretion of the gastric juice. He proved this by withdrawing the gastric juice produced during simulated feeding and then introducing it into a dog that had not been esophagostomized but lived under normal conditions. He observed that in this dog there were signs of degeneration and even extensive erosions of the mucous membrane of the fundus of the stomach, although they were of a somewhat lesser degree than in the esophagostomized dogs. He thinks that this experiment proves conclusively that a healthy gastric mucous membrane can be impaired by a hyperacidic gastric juice. That the condition of starvation is likewise a causal factor of the degenerative processes was proved by starvation and thirst tests on dogs that had not been esophagostomized. In these dogs there was a high degree of gastric acidity even when the dogs no longer showed a desire for the meat that was shown to them. The tissue changes in the gastroduodenal mucous membrane during starvation resemble those in the esophagostomized dogs but are of a somewhat lesser degree.

Surgical Operations During Menstrual Period.—In order to detect the influence exerted by surgical trauma during menstruation, Popova made careful observations on women in whom an operation was urgent and could not be postponed until after the menstruation. The favorable course of the postoperative wound healing observed in these cases induced him to operate on women during the menstrual period also when the intervention could have been postponed. On the basis of observations in fifty cases he reaches the following conclusions: In menstruating women there is a more intense stimulation of the hematopoietic apparatus than in women who are operated on during the intermenstrual period. This increased stimulation becomes manifest in a more pronounced leukocytosis and in a greater deviation to the left in the hemogram. These manifestations are especially noticeable in cases in which general anesthesia is employed. The coagulability of the blood increases under the influence of the surgical intervention in menstruating women in the same degree as in nonmenstruating women. The danger of a hemorrhage during the intervention is of no great significance, in spite of the fact that thrombopenia develops in some cases. Provided the intervention is not of an especially serious nature, the menstruation does not cause complications during the postoperative course. In view of the biologic peculiarities of the menstrual period it is advisable to avoid serious, long lasting surgical intervention, unless an immediate intervention is absolutely necessary. However, less complicated and minor interventions are not contraindicated during menstruation.

Percutaneous Nailing of Dislocated Fragment of Lower End of Tibia.—According to Felsenreich, luxation fractures in the upper portion of the ankle joint with avulsion of longitudinal portions of the tibia have a tendency to reluxation, in that the fragment becomes dislocated again, a condition that is designated as "wandering talus." Treatment with a plaster-of-paris cast, following manual reposition, gives good results in some cases; however, in many instances it is followed by secondary dislocation and leads to permanent difficulties. The simple extension treatment, which accomplishes reposition by slow traction, avoids serious permanent impairment but leads to step formation in the joint by causing a slight displacement of the talus and posttraumatic arthritis. Böhler's procedure of reposition by screw traction in the plaster-of-paris cast and subsequent permanent extension secures ideal primary results, but in severe cases the fragments cannot be permanently retained in the correct position. For this reason the author combined the latter method with the percutaneous nailing of the detached fragment with the aid of a wire, which is tightly stretched and fastened on the plaster-of-paris cast. This procedure prevents the secondary displacement of the fragment, and the final results meet all expectations by reestablishing normal anatomic as well as functional conditions.

Severe Polyneuritis Following Use of Abortifacient. H. Jagdhold. —p. 623.

Relation of "Epiphrenal Syndrome" to Cardiospasm.—Von Bergmann challenges the old theory of cardiospasm. He questions both that it is a spasm and that it is a disturbance of the cardia. In ten of seventeen cases of so-called cardiospasm, he observed that when in roentgenoscopy a maximal filling of the esophagus was avoided a winding structure was noted above the diaphragmatic hiatus, and he thinks that this is a portion of the stomach, for if in such cases the cardia is searched for, it is far above the diaphragm. The author points out that both vagi go through the esophageal hiatus of the diaphragm, and that pressure or pulling at this site may cause vagal and also sympathetic reflex phenomena, for the two vagi contain not only centrifugal vagal fibers but also centripetal fibers and sympathetic fibers. The author cites experiments in which a balloon was introduced into the esophagus where it passes through the diaphragmatic hiatus. It could be observed that the coronary circulation was considerably inhibited as the result of the pressure on the vagi. If angina pectoris is caused by a disturbance in the coronary circulation, as is assumed by some, this experiment would explain the angina pectoris of the gastrocardial syndrome. Other conditions that the author thinks are due to pressure in the diaphragmatic hiatus are gastric vertigo, many cases of periodic hiccup, also aerophagy and nervous eructation. The author considers the cases in which he observed a portion of the stomach above the diaphragm not as true diaphragmatic hernias but rather as transluxations caused by a contraction of the longitudinal muscles of the esophagus. This theory of pathogenesis is corroborated by the frequency of the phenomenon as secondary disease following peritoneal vomiting, ileus, gallstone colic and postoperative conditions. However, it is not definitely known as yet how often transluxation of the stomach actually exists and the author prefers the term "epiphrenal syndrome," which is more general and which may have various forms of manifestation. In regard to the treatment, he states that those measures are suitable which are resorted to in cases of the gastrocardial syndrome. He also thinks that special diaphragmatic gymnastics might prove helpful. Surgical intervention is necessary only in the severest cases.

Relation of Osteitis Fibrosa Generalisata and Parathyroids.—Wichmann describes a case of osteitis fibrosa generalisata (von Recklinghausen) in a woman, aged 45. Following removal of an intrathyroidally located adenoma of the parathyroid from the left side of the thyroid, which was slightly enlarged, there was a progressive improvement in the general condition, and the greatly changed calcium metabolism returned to normal. This case again brings out the close relations of osteitis fibrosa generalisata and the parathyroids and shows that surgical removal of a pathologically changed parathyroid, even if it is intrathyroidal and only slightly enlarged, can achieve a successful result. This case also shows the importance of a thorough examination of the thyroid to locate the parathyroids when these appear to be absent. A wedge-shaped excision of any suspicious portion of the gland, especially on the posterior wall, is advised.

Rovsing's Sign in Diagnosis of Acute Appendicitis.—Wallerström discusses the Rovsing sign in acute appendicitis and calls attention to its diagnostic value. Rovsing's sign consists in a sensation of pain on the right side of the abdomen at the site of the appendix evoked by light pressure in the left iliac fossa. The author procured the best results by slowly pressing the soft parts over the colon downward with the fingertips and then quickly releasing them. The sensation of pain at the site of the appendix occurs at the instant of release. Perman's method of light downward pressure in the left iliac fossa in the direction of the right side of the abdomen was also used with better result than the original pressure and massage method of Rovsing. Investigations were made in 211 operative cases of acute appendicitis. Rovsing's sign was exhibited by 70 per cent of the cases. Rovsing's sign was positive in a higher percentage of cases in gangrenous appendicitis than in simple appendicitis. Of the other appendicitis symptoms, only pain on the right side of the abdomen and direct local pressure sensitivity in the right iliac fossa compare with Rovsing's sign in frequency. Rovsing's sign is frequently positive when other appendicitis symptoms are negative. It is probably evoked by a pressure transmitted from the left to the right side of the abdominal cavity and is probably comparable to direct pressure sensitivity although the mode of producing the pressure is somewhat different. The occurrence of Rovsing's sign is probably favored by a medial or lateral position of the appendix. The sign is not specific for appendicitis, as it may be found in other localized disturbances of the peritoneum. It is a means of differential diagnosis between extraperitoneal and intraperitoneal disease conditions. Negative result of Rovsing's sign does not exclude appendicitis, but a positive Rovsing's sign is a valuable aid to diagnosis and indicates that the pathologic changes are in the appendix. There are cases in which the positive Rovsing sign is the only unequivocal symptom of appendicitis.

*Vaccine Therapy of Whooping Cough. E. G. Westendorff.—p. 261.
*Idem. H. Gentzsch.—p. 273.
Treatment of Whooping Cough. E. A. Voss.—p. 287.
Percentage of Children Having Had Scarlet Fever: Epidemiologic Significance of That Percentage. G. Fedders.—p. 294.
Physical and Mental Action Capacity of Girls in Elementary Grades in Relation to Their Constitution and Health. Else Liefmann.—p. 305.
*Etiology of Necrosis of Subcutaneous Adipose Tissues of the New-Born. E. Unshelm.—p. 321.

Vaccine Therapy of Whooping Cough.—Numerous reports of experiments with nonspecific protein therapy in whooping cough induced Westendorff to try this treatment in fifteen cases of the disease. In intervals of from two to three days he injected increasing doses of a polyvalent gonococcus vaccine, but there was no noticeable change in the course of the disease. Several months later the author treated twenty whooping cough patients with a specific whooping cough vaccine. Only in two of these children was the whooping cough favorably influenced; in all others the treatment was ineffective. In a case of tuberculosis of the bronchial lymph nodes, in which whooping cough vaccine was given to prevent whooping cough, it developed nevertheless two weeks after the first injection. However, in view of other favorable reports in the literature, and considering the two cases of his own observation, the author does not feel justified to consider the vaccine therapy of whooping cough as entirely valueless. He considers as a distinct disadvantage that in most cases whooping cough is not recognized until it has fully developed but he hopes that, eventually, careful consideration of the anamnesis, examination of the hemogram (increased number of leukocytes) and perhaps also bacteriologic examination may permit an earlier diagnosis. He hopes that, if the vaccine therapy is begun in the earliest stages, it may prove more effective.

Vaccine Therapy of Whooping Cough.—Gentzsch employed both a mixed whooping cough vaccine and a pure vaccine. The mixed vaccine contained mainly Bordet-Gengou bacilli but also pneumococci, streptococci, staphylococci, influenza bacilli and Micrococcus catarrhalis. The pure vaccine contained only Bordet-Gengou bacilli. Both vaccines were given in increasing quantities. Among forty-eight children who were treated with these vaccines, the author observed twenty-six in whom the duration of the disease was shortened. The course was the shorter, the earlier vaccination was begun. In children with complications the shortening was less, and in nurslings the vaccine had no effect. Early treatment was successful in a few cases. Secondary effects, such as local reactions, increase in temperature, increased frequency and intensity of the attacks of coughing during vaccination but also a favorable influence on the state of nutrition were observed in several of the cases. When larger doses of vaccine were given, the actions were the same as those observed with the usual doses. Three of the children who underwent the vaccine therapy died. However, two of these fatalities occurred six months after the vaccination, and these children had miliary tuberculosis; the third fatality resulted from a meningitis that developed on the day following the second injection of vaccine.

Necrosis of Subcutaneous Adipose Tissues of the New-Born.—Unshelm states that the majority of those who have studied necrosis of the subcutaneous adipose tissues in the new-born think that it is caused by a trauma, particularly by a birth trauma, but there are also some who dispute this etiology. The author reviews a case history from the literature, in which the necrosis of the subcutaneous tissue of the new-born was identical with the fat necrosis in adults, which is often an accompanying symptom of a pancreatic disorder. However, in adults there are also fat necroses that are not of pancreatic origin, and these are often ascribed to traumatic causes. The etiology of the necrosis of the subcutaneous adipose tissue in the new-born is still not definitely decided, but the following are the factors that have been cited to prove a traumatic origin: 1. In the majority of the cases that have been described in detail the birth had been difficult, the infants had been more or less asphyctic, and besides this other birth traumas were present. 2. The mothers were usually old, corpulent primiparas. 3. The infants were generally large and heavy and had a well developed subcutaneous layer of fat. 4. True traumatic changes, such as the so-called forceps infiltrates, were found similar to the necrosis of the subcutaneous adipose tissues. 5. The children were frequently exposed to intensive cooling, and by artificial cooling it was possible to produce similar changes. However, the following factors have been cited against the traumatic origin: 1. Incongruity between the trauma to be expected and the actual trauma. 2. The occurrence in apparently easy spontaneous confinements. 3. The symmetrical localization. 4. The missing histologic proof that the forceps infiltrates and the indurations resulting from cooling are identical with the necrosis of the adipose tissues. Before discussing the pro and con of the traumatic etiology, the author describes five cases of his own observation. In spite of the fact that the last described case has several characteristics that speak against a traumatic origin, the author considers such an etiology nevertheless possible. He thinks that the impaired circulation as a result of detachment of the placenta may have caused the necrosis in this case, and in general he inclines to the theory of a traumatic etiology; but he considers a correction of the opinions about the harmlessness of the birth process of greater importance than a theory on the etiology of the necrosis of the subcutaneous adipose tissue in the new-born.

Pharmacologic and Bacteriologic Tests of Iodoform Gauze.—In summing up the results of his pharmacologic and bacteriologic tests, Franz states that the iodoform content of the gauze in many instances is not what it is declared to be. The discrepancy is frequently considerable in gauze that has been stored for some time, as well as in that which has been produced more recently. The wrapping of iodoform gauze is significant for its content in iodoform as well as for the sterility. Wrapping in wood fiber paper that is free from sulphide and in thick, black parchment paper appears most suitable, but the author considers a third covering with cellophane advisable. The question whether and how long pathogenic organisms can live in iodoform gauze has as yet not been definitely decided, but it is probable that the bactericidal power increases with the iodoform content. However, in spite of the greatest care in the preparation of iodoform gauze, it cannot be entirely sterile for the finished product cannot be sterilized by steam. Whether the iodoform gauze that appeared to be sterile was actually sterile must be questioned, since free iodine may have inhibited the growth of the bacteria. The author recommends that efforts should be made to replace iodoform gauze by a gauze that, following impregnation with a disinfectant, can be sterilized. He suggests several disinfectants that might be used, but it is as yet not proved whether these disinfectants have the same hemostatic and deodorizing effects as iodoform.

Successful Replacement of Knee Joint by Ankle Joint.—In the case reported by Demel and Gold, the right leg of a person, aged 22, had been atrophied since birth. The atrophy involved mainly the femur. The prosthesis that the patient wore was unsatisfactory in that it did not permit bending in the region of the normal knee joint. To overcome this difficulty the authors resorted to an operation that had first been done by Borggreve in 1929, namely, replacement of the knee joint by the ankle joint, after the latter had been turned round. Thus the ankle joint acted in the direction of the knee joint and permitted the wearing of a prosthesis that was movable in the knee joint. The operation was done in two stages and the results were entirely satisfactory.

Spontaneous Separation of Entire Omentum.—Esau describes a disorder that so far has not been reported; namely, detachment of the omentum and torsion of a narrow strip. With the exception of a slight irritation of the peritoneum, which became manifest in the later stages and which was interpreted as appendicitis, there were no clinical manifestations. The patient was a lumber worker, aged 47, who was brought to the hospital with the signs of a not entirely typical appendicitis and who reported that about two months previous he had had a similar attack, which, however, had disappeared again following three days of rest in bed. Since during the second attack there were no severe symptoms that necessitated an immediate operation, an expectant attitude was assumed and the symptoms disappeared again. However, a surgical intervention was recommended to the patient, and he consented. The operation revealed that the omentum was detached and had become implanted between the ascending colon and the lateral abdominal wall, where it had formed adhesions with the adjoining tissues. Upward it reached to the liver, and below it ended in a pedicle, which showed torsion and the point of which was fastened near the inguinal ring on the right side. The entire omentum with the exception of the narrow attachment had become necrotic. The omentum was removed and the recovery was uneventful. The operative specimen weighed 1,100 Gm. The author describes the results of the histologic examination and in discussing the case history he states that the patient had an inguinal hernia on the right side. He considers this factor significant for the etiology, since persons with inguinal hernia of the right side are predisposed to torsion of the omentum.

Pyosalpinx in Inguinal Canal with Aspects of Nonreducible Inguinal Hernia. E. Fauvet.—p. 950.

Action of Calcium in Pulmonary Infarct.—Hubrich relates that in a postoperative, embolic, hemorrhagic infarction of the lung, timely intravenous and intramuscular injection of normal calcium gluconate had a life saving effect. He emphasizes the complete absence of reaction in intravenous as well as intramuscular injections. He therefore advises the use of calcium gluconate as a hemostatic, especially in nervous patients with severe hemorrhages and with threatening collapse.

Distinct Sign of Certain Fractures of Scapula.—Comolli points out that the diagnosis of fractures of the surgical neck of the scapula is considered difficult. Because of the lack of distinct signs and because of the nearness of the joint it cannot be readily differentiated from a contusion, from a luxation of the scapula, and from fractures of the upper end of the humerus. Most authorities think that for a definite diagnosis roentgenoscopy is necessary. However, the author observed an unmistakable sign, on which the diagnosis of fracture of the scapula, more particularly fracture of the surgical neck, can be based with certainty. This sign is a typical swelling, which develops in the region of the involved scapula shortly after the trauma. The swelling, which indicates the triangular outline of the scapula, is due to the fact that blood from the fracture gathers before as well as behind the scapula. As a result of the peculiar anatomic conditions this blood cannot escape and a cushion-like swelling, corresponding to the outline of the scapula, is the result. The author cannot state with absolute certainty whether this sign is noticeable in all cases, though in view of the manner in which it develops, this is probable; but in compound fractures with considerable tearing and displacement, it may not be so noticeable.

Catatonia in Dementia Paralytica.—Bornstein describes five cases of young adults with dementia paralytica and with catatonic syndromes. He points out the insufficiencies in the theories relating to these syndromes. The psychologic theory (Boestroem) is founded on disturbances of volition and on the analogy with normal life, but it omits the causes of catatonia. The anatomic theory (Wernicke, Kleist, Satio, Kalnin) is not yet uniformly elaborated. From the latest investigations, however, it appears that anatomic changes, alone, cannot be considered as fundamental factors in exciting catatonia in dementia paralytica. De Jong and Baruk see in this syndrome an expression of intoxication, undefined as yet but attacking in the first place the cortex of the brain. The author thinks the last standpoint to be acceptable, namely, that the infection in young adults causes humoral changes, as yet unknown, which by their action on the cortex may, in certain predispositions, provoke catatonic syndromes.

Kazansky Meditsinsky Jurnal, Kazan

28: 1-100 (Jan.) 1932. Partial Index

*Local Anesthesia in Surgery of Biliary Tract. A. V. Vishnevsky.—p. 57.
*Tying Fallopian Tubes and Subsequent Permeability. Kh. Kh. Meshcherov.—p. 66.

Local Anesthesia in Surgery of Biliary Tract.—Vishnevsky states that, in typical cases of disturbance of the biliary tract with a definite diagnosis, the operation of choice consists of an incision downward from below the ribs; in patients with a questionable diagnosis and an obscure clinical picture with regard to the biliary system, necessitating an abdominal exploration, the operation of choice consists of a median incision and local anesthesia according to the method described in the *Kazanskiy Meditsinskiy Jurnal*, 1929, number 9. He believes that local anesthesia makes possible a subserous cholecystectomy and subsequently an hermetic closure of the abdominal incision. Preliminary anesthesia of the gallbladder makes possible a subserous cholecystectomy which under ordinary conditions may be difficult or impossible. In cholemic patients with an intact wrinkled gallbladder containing calculi, transduodenal choledochotomy as well as tying of the cystic duct is the only intervention that makes it possible not only to regulate the passage of the bile into the intestine but also to close hermetically the abdominal incision. The author believes that his method of local anesthesia decreases the chances of hemorrhage. Mobilization of the duodenum and the head of the pancreas makes this intervention quite simple. The method of progressive infiltration anesthesia together with diffuse impregnation of the tissues not only makes orientation of tissues less difficult but aids in the exposure of the gallbladder and bile ducts, simplifies the subserous isolation of the gallbladder, increases the view of the duodenal area, enables a more careful exploration of the ducts, and makes possible a bloodless mobilization of the duodenum and the head of the pancreas.

Tying Fallopian Tubes and Subsequent Permeability.—Meshcherov describes the technic, the microscopic observations and the general results in the tying of the fallopian tubes in twenty-six female rabbits. Although he does not believe that the results in animal experiments can be carried over to human beings, he concludes that an operation with tying of the fallopian tubes as a method of sterilization of women cannot entirely guarantee against subsequent conception and therefore should not be used for that purpose. In view of the large number (nineteen of his rabbits) of instances of atresia of the tubes, the author concludes that obliteration of the fallopian tubes does not prevent permeability. Closure of the opening at the site of the ligature and subsequent obliteration of the fallopian tubes may be the cause of the yearly increase in the number of ectopic pregnancies.

Diuretic Action of Merbaphen and Mersalyl. B. Shklyar.—p. 92.

Doses of Digitalis in Cardiac Disturbances.—Abdulaev examined the histories in 500 cases of cardiac disturbance treated with digitalis (pulvis foliorum digitalis) during one year or longer. The material was divided into three groups: Group 1 consisted of patients with decompensated mitral lesions complicated with fibrillary arrhythmia; group 2 was similar to group 1 but the patients had normal cardiac rhythm; group 3 consisted of patients with cardiosclerosis with cardiac insufficiency and fibrillary arrhythmia or normal rhythm. In conclusion the author states that treatment at the onset should consist of large doses of digitalis (0.1 Gm. three times a day) in order to store a sufficient quantity of the drug in the organism. This dose does not have to be administered over a prolonged period; in most cases, sufficient action is evident after from five to six days' treatment. It is necessary to decrease the dosage gradually to 0.05 Gm. two or three times a day and to bring about a bradycardia of from 60 to 70 beats a minute. If the heart beats decrease to less than 70 a minute, it is advisable to interrupt the digitalis for three or four days. Further treatment should consist of doses such that daily administration over a long period would be effective without evidence of toxicity. The author finds this dose to be from 0.1 to 0.15 Gm. a day, depending on the individual. In the treatment of patients with valvular lesions but without fibrillary arrhythmia this may be the beginning dose, but for maintaining the effect a larger dose is necessary (0.05 Gm. three times a day to 0.1 Gm. twice a day). In arteriosclerotic cardiosclerosis it is necessary to remember that digitalis may cause cardiac spasm, degenerative changes in the myocardium and changes in the impulse of the cardiac system.

Pituitary Extract in Treatment of Gastric Ulcer.—Rapoport states that disturbances in the function of the gastro-intestinal tract may be understood through the study of the neuroglandular apparatus; that is to say, the endocrine glands and the sympathetic nervous system. Believing that the posterior lobe of the pituitary body influences gastric secretion, the author studied the results following the injection subcutaneously of 1 cc. of solution of pituitary, once a day, twenty minutes before the main meal, and the treatment continued for from four to six days. Examinations made at various intervals after the first injection included a determination of the gastric acidity and the free hydrochloric acid and a study of the secretory and motor functions. He concludes that solution of pituitary results in a decrease in the gastric acidity and the free hydrochloric acid under normal and fasting conditions. In some instances the decrease in acidity is apparent only after several injections (the first may sometimes increase the acidity). The changes in the acidity remain after the treatment has been discontinued. Treatment with solution of pituitary does not bring about those changes in gastric motor activity that would contraindicate such treatment, nor do the doses used cause any accidents. The author does not claim specificity for this treatment; however, since solution of pituitary has the power to inhibit secretion it can be efficacious in the treatment of ulcers, through humoral and especially nervous influence on gastric secretion.

Constancy in Basal Metabolism.—Rozenblum states that he finds no uniformity in the literature with regard to constancy of basal metabolism in the same patient over a prolonged period of time. On himself and a laboratory assistant, he recorded the caloric energy required for twenty-four hours and found that the variations during one year ranged from 10 to 15 per cent of the original value. He believes that fluctuations in the metabolic rate due to objective and subjective stimuli should be considered in clinical diagnosis and that the basal metabolism should be observed not at one but at several examinations.

Causes of Blindness in Faroe Islands. R. K. Rasmussen.—p. 79.
*Demonstration of Bacillemia. J. Holm.—p. 92.
*Clinical Investigations on Temperature of Skin, Especially in Tuberculosis of Joints and Bones. J. Foged.—p. 107.

Demonstration of Bacillemia.—In 208 patients, mainly with tuberculous disease, Holm failed to demonstrate tubercle bacilli in the blood on cultivation according to Löwenstein's method; in forty-two of these, tubercle bacilli could not be demonstrated by simultaneous inoculation of the precipitate in guinea-pigs. In eighteen patients with progressive pulmonary tuberculosis in the third stage, bacillemia was not demonstrable by direct inoculation of the blood in guinea-pigs and cultivation in Besredka's substrate. In thirty-nine patients, chiefly with tuberculous disorders, the blood was examined after treatment with citrated water; tubercle bacillemia was established in two cases. The author concludes that tubercle bacillemia is not a frequent occurrence in tuberculous disease.

Temperature of Skin, Especially in Tuberculosis of Joints and Bones.—Foged states that in cases of active tuberculosis of the knee, ankle and foot there is an abnormal local increase in the temperature of the skin. In tuberculosis of the elbow, wrist and hand the symptom is less constant. The numerical value of the symptom corresponds to the degree of the disease. Measurement of the local temperature of the skin is only a supplementary examination, to be evaluated in relation to the other clinical results.

SURGICAL VISION

CHAIRMAN'S ADDRESS

HUBERT A. ROYSTER, M.D.
RALEIGH, N. C.

"The present is in every age merely the shifting point at which past and future meet and we can have no quarrel with either." In these words of Havelock Ellis there is contained the germ of an inspiration which should find lodgment and growth in the consciousness of all who are deeply concerned with their work in life. Therein is expressed the true conception of what men call vision. This means literally seeing backward, seeing now and seeing forward, and then harmonizing the relations of each objective. Just as in ocular vision one does not see with the eye but with the brain, so in the larger realm vision depends on the higher virtues of character, philosophy, discernment and understanding.

For the surgeon, vision is a vital requirement. The ability to see behind, through and beyond the problems presented to him is the true test of his mastery of his profession. Unless he knows something of what has gone before him, he knows very little of what is going on around him, and can hardly visualize what may come to him. Preparation, training and experience, the necessary factors in the surgeon's equipment, are but part and parcel of a refining process, pointing to that perfection of vision which is wrapped up in knowledge of the past, realization of the present and foresight of the future.

The study of surgical history furnishes a bountiful background for the development of a career, and, as history is largely biography, an intimate acquaintance with the worthies who have gone before brings a satisfying sense of struggle that denotes success. Not otherwise could one learn that often the true is not new and the new is not true. The evolution of surgery has had its ups and downs, slow at times, rapid at others, and even recently accelerated developments will soon become ancient history. Some of those who predicted that there were no more surgical worlds to conquer lived to see their prophecies nullified. Past performances are stepping stones, not the journey's end. Likewise, the literature of surgery, especially that in periodical form, yields its own reward to those eager students who delve into its pages. Familiarity with records of the past confers an aristocracy on the possessors of such knowledge. It may be humiliating to present what is regarded as a rare occurrence only to be reminded that several scores of years before many similar instances had been published. This is pointed out to place no damper on the reporting of independent observations as additions to the surgical literature, but only to afford encouragement toward a broader vision. Intensive perusal of contemporaneous surgical literature reveals references to older records and impels a desire for closer study.

In the glowing present surgical vision beholds the actual patient and bestows on him all the resources of head, heart and hand. What has been put in previously as preparation and training comes out, no more, no less, as the art of discrimination, the capacity to apply general knowledge to a particular situation. Here is occasion for the deepest insight, a challenge for thought, for decision, for action. The surgeon is his own supreme court, in session every day, and unless he is imbued with "the heavenly vision," a combination of tradition, courage and inspiration, he will fail in his great adventure. The readiness which says, now and here, that this or that must be done is born of a sound sanction which selects the consciously right and rejects the obviously wrong, irrespective of rule or theory, and devotes an educated judgment to the immediate problem. Mr. Kipling well said to the Royal College of Surgeons: "Your dread art demands the instant impersonal vision which in one breath, one beat of the pulse, can automatically dismiss every preconceived idea and impression, and as automatically recognize, accept and overcome whatever of new and unsuspected menace may have slid into the light beneath your steadfast hand." The deadly taint of standardization furnishes no shrine for worship in surgery. It is fatal to a liberal vision, founded on a life's labor and a single-minded adherence to truth.

When the surgeon brings his vision to bear on the future he must needs think in terms of experiment and research. No advancement in science is attainable except along the path of trial and error up to fact. Surgery dare not boast of its practical accomplishments as belonging narrowly to its own sphere, but must give credit to the auxiliary sciences the researches of which preceded and still attend its forward strides. Without Pasteur, the chemist, there could have been no Lister, the surgeon. One speaks magnificently of practical results, but behind them stands an array of theories and experiments which seemed at first of small importance, thought out by workers who had the bravery to believe in their final utility. When Faraday was asked by an inquirer observing his experiments in magnetism, "What is the use of it all?" the famous scientist replied, "Will you tell me the use of a newborn child?" There are definite problems continually arising in surgery which are to be solved by surgeons themselves, but always in the spirit of science and with

---

Read before the Section on Surgery, General and Abdominal, at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

a clear vision of reality. John Galsworthy has expressed this forcibly: "Only one who experiments out of the sheer necessities of his theme will create that which will last. They who experiment from a mere craving for novelty, capture for a season the intelligence of the weaker brother, and attract the butterflies of the day; but their works fade like dew off the grass when the sun shines."

No one could for a moment justly disparage the value of experimentation. It has led to innumerable discoveries, to the correction of serious inaccuracies, to the saving of lives. Yet certain types of research have gone up blind alleys for lack of purpose, for lack of a compelling aim, for lack of vision. There is wanted as much wisdom to see the irresistible demand for instituting a research problem as there is to conduct the experiments and interpret their findings. The fetish of statistics has done much to confuse the pictures presented in surgical research. A parade of animal experiments, a row of figures and tables, together with elaborate conclusions, may mean a great deal or nothing at all, subject to the character, the environment and the material of the individual investigator, and, further, to the proper analysis of reported statistics themselves. May not one intelligent man's conscientious opinion be of parallel value? May not vision be needed as a control factor in experiment? We hug to our bosoms the research worker in surgery who is possessed by an idea, whether it be simply a hypothesis or an actual issue, and who follows it through with unerring faith to the end, but we deprecate the trumping up of a meaningless problem only to exploit a theme which had better remain unsung, or to prove a point which needed no proof. Let us recall the earliest announcement of Hippocrates concerning surgical research: "phenomena first, then judgment, then general propositions, then practical knowledge and craft."

If, then, surgical vision derives its impulse from a conception of past, present and future, there is room for its fulfilment in surgical practice. There are three essential ingredients in the make-up of the surgeon—the mental, the moral and the mechanical. The first has to do with knowledge, the second with judgment and the third with skill. In such order they provide the why, the whether and the how of every surgical question. A well rounded surgeon recognizes this trinity of attributes and happy indeed is he—and rare in the extreme—who may possess them all in equal degree.

The mental vision that brings resource, common sense and clear thinking to bear on finding the cause, designating the disease and relieving the patient represents the surgeon's primary investment, enveloping his every thought and deed like a well fitting garment. The mind must conceive the act and mature it in the light of independent intelligence founded on valid principles. Let this be the guiding motive in the surgeon's career: to do his own thinking, his own operating and his own deciding. After all, a surgical operation is a one-man job. Team work is essential; assistants are required, but the operating surgeon in the individual case is the responsible actor; his mind carries through; other minds are merely adjuncts. Only one can do the operation; the others assist the operator and fall in with his plan. The newspapers may still report that "Doctors Brown, Jones and Robinson operated on Mrs. Smith yesterday," but we know that there was one operator, with two assistants performing their cooperative offices; otherwise, there was a syndicated enterprise with no leading spirit. The surgeon's mind must be open to suggestions, but his own ripened resourcefulness may afford him the wisest advice. When there is no surgical vision, the patients perish.

The moral attitude of the surgeon tells tremendously in his work. It supplies the qualities of judgment, accuracy and honesty. Surgical judgment has been the topic of many discourses, and different views have been held in regard to its significance. It is inherently a moral manifestation, for it has to do with a righteous intent to choose the wise course regardless of everything but the patient's well-being. Since at any moment during the consideration of a particular case the surgeon may be called on to exercise his conclusive judgment, either deliberately or instantly, and since serious consequences usually are involved in his decision, it behooves him to keep a keen edge on his surgical conscience, leaving out all matters of selfish interest or the importunities of the patient and his family. Thus is judgment displayed by the surgeon in his most exalted capacity.

Accuracy in the surgical scene stands for an ardent yearning to do the right thing in the right way at the right time. To be accurate is to care above everything for the truth in thought, action and attitude. "To think free is great; to think right is greater." Honesty of intellect is probably the profoundest type of honesty, because it is inclusive and supplies the basis for self-control, the finest of all human virtues. The surgeon who is honest with himself cannot acknowledge slipshod counsel, advise unnecessary operations or forget the person of his patient. No unworthy sentiment or mercenary desire can enter the sensorium of the honest surgeon, for he hears the Spirit of Science calling: "I am what is, what shall be, what hath been. My veil hath been disclosed by none. The fruit which I have brought forth is this: the sun is born." But greed and dishonesty will destroy every one of our visions. Our hope is to see, to know, to feel the light.

What may be called the mechanical side of surgery is not without its need of an understanding vision. Surgery is not wholly mechanical. Surely it is not all of surgery to cut, nor all of operating to perform the operation. It is true that whether a surgical procedure is topical, manipulative or operative, it necessarily requires some knowledge of mechanics; however, this may be acquired in sufficient degree by the average person in his training until the processes become automatic, allowing occasion for the development of attainments higher than the inanimate practices of the ordinary mechanic. The components of the mechanical aspect of surgery which must be mastered before skill in the art can be attained—and they are the accomplishments of every other artist—are coordination, precision and timing. Proper coordination between brain and fingers is the surgeon's peculiar endowment. The faultless response of hand and head makes for the consummation of what is called surgical technic, which is not altogether mere mechanics. Now vision plays its hand, telling what comes next, giving that sense of familiarity which breeds repose. Precision, the practice of exactness, lends to the art of surgery a feeling of security, which should anticipate the happening of the unexpected, and of deliberation, which should not be translated into delay. Being precise implies doing as much as, and no more than, indications admit and therein lies a lesson for surgeons who would win success. The special genius of timing is a gift of choice excellence, the faculty of adjusting coordination with precision so as to complete the procedure safely, speedily and successfully. In sport it means getting there just ahead of the ball or the player; in surgery it means knowing how to combine the automatic with the deliberate parts of an operation in just proportion. The talent of timing is commended to those surgeons who, on beginning an operation, seem to love it so longingly that they dislike to get through with it, but continue to pat and fondle the tissues assiduously and cease reluctantly after the period of limitation has expired, if not the patient.

Vision in surgery, therefore, is justified of its believers. Vision leads; performance follows; achievement abides. The greatest of these is vision. Its most natural and most important function would inspire a look into the future. Who knows what it holds? Certain it is that we are now in a changing age. Advancements in the science and art of surgery are the order of the day and new ideas are constantly in the making. Whether the trend will be in the direction of more operative surgery or less, no one may surely say; but there is such a thing as preventive surgery, done early or avoided entirely, and it may be that in the distant view our supreme aim will be to reduce the number of surgical operations and to raise the percentage of surgical meditations. As we go along, let us take with us surgical vision, permitting it to show the way, for

> "To keep in sight Perfection and adore
> The vision is the artist's best delight."

THE CONTROL OF PELLAGRA

G. A. WHEELER, M.D.
Surgeon, United States Public Health Service

AND

W. H. SEBRELL, M.D.
Passed Assistant Surgeon, United States Public Health Service
WASHINGTON, D. C.

The underlying factors concerned in the prevalence of pellagra fall into two classes, which from the standpoint of public health must be viewed from different angles.

There is a small, but not an inconsiderable, number of cases which arise from conditions peculiar to the individual. Among these are dietary eccentricities and idiosyncrasies, food fads, obsessions, alcoholism, gastro-intestinal disease and other disturbances resulting in a disordered diet. These are isolated, or sporadic, cases and may occur anywhere, at any season and without reference to financial status or dietary surroundings. Conditions of this nature do not usually come within the scope of public health activities, and such cases may therefore be excluded from further consideration in this connection. Their prophylaxis and treatment are matters for the attention of the family physician.

On the other hand are the cases which arise from conditions more or less common to groups of individuals, such as households, certain institutions and sometimes the major element of the population of relatively large areas. Chief among such influences may be mentioned limitation of the kind and quantity of food crops produced, resulting in an undue restriction in variety, lack of availability of certain essential foods and foodstuffs during certain seasons, adverse economic conditions with reduced purchasing power and a general lack of thrift with its resultant impoverishment and malnutrition. These far-reaching and interlocking factors constitute the source of origin of endemic pellagra, which accounts for perhaps more than 98 per cent of all pellagra, and present a cross-section view of the conditions dominating the problem of its control.

The latest complete figures relating to the annual death toll from this disease in this country are those for 1930. During that year 7,146 deaths were recorded. The most reliable morbidity data available indicate that for each death there were not less than 35 cases and for every case a large number of patients who suffered from minor degrees of malnutrition and debility. There are few conditions more pathetic than a neglected case of pellagra, and perhaps no place in more urgent need of practicable corrective public health measures than a neglected pellagrous community. In no disease is the response to proper treatment or prophylaxis more gratifying. The lowered physical and mental standards and the reduced capacity for the enjoyment of life render its economic and social aspects of pressing importance in endemic centers. As a remediable cause of insanity it offers a most fertile field for constructive work in mental hygiene.

Of the 7,146 deaths reported, 7,000 (or 97.9 per cent) occurred in those states which lie wholly or partially within the cotton belt, and of these the vast majority occurred in that portion of the cotton belt actually engaged in the production of cotton. The next most prolific source is the smaller and more isolated rural industrial communities of the South. Pellagra never has been a problem in strictly urban centers regardless of their location or environment.

In clearing up its etiology, Goldberger and his associates, of the Public Health Service, have shown repeatedly:

1. Pellagra can be prevented at will by the simple addition of any one of several known articles of food to the dietary on which it developed.
2. It can be produced at will in persons never before involved by the removal of these items from the habitual diet, even though their chemical and energy values are fully compensated.
3. There is a specific water-soluble and heat-stable accessory food factor of the class known as vitamins concerned in its production, this factor being sufficiently abundant in those diets which prevent pellagra and low or lacking in those which fail to prevent it.

These are cold, hard facts based on a wide assortment of direct experimental evidence which may be regarded as a standard of quality in scientific medicine. The conclusion that the disease is due to a specific dietary fault is therefore not only unavoidable but inevitable, and any control measures which are not planted squarely on this conception of its origin can never hope to succeed.

Summarizing the foregoing, it is seen that pellagra is one of the leading causes of death and disability throughout much of the rural South, that it may be uniformly prevented by the use of any one of several supplemental foods and that the basic dietary conditions most favorable for its development are those which prevail in those sections in which cotton production is the principal agricultural pursuit.

Knowing the nature, source and means of prevention of this veritable public health scourge, the question of why more progress is not being made in its permanent control might fairly be asked. It is no difficult

---

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932.

matter to map out a program designed to wipe out pellagra from any given section within a very short time, but devising a suitable program for its eradication and effectively carrying it out under the conditions prevailing are two entirely different propositions. No problem so intimately bound up with economic conditions, agricultural practices and dietary customs, which themselves are hard to alter, can by any means be classed as a simple and easy undertaking. It may sound simple enough, but it has obstacles which are not encountered in the usual preventable diseases. Not the least of these is that whatever permanent success is attained, the people involved must, themselves, ultimately play the essential rôle.

Under institutional conditions, where the diet is under centralized control, the problem of pellagra can be eliminated promptly. This was amply demonstrated by Goldberger and his co-workers in connection with the establishment of its etiology. Utilizing this knowledge, our insane asylums, homes for the indigent and orphanages, in which pellagra was formerly a most serious problem, have been able to control it in a satisfactory manner. By a few simple and comparatively inexpensive additions to the daily menu, one state institution for the insane, the largest in the South and the second largest in the country, has reduced the annual death rate from pellagra from 6.2 per cent of all inmates to as low as 0.1 per cent, this in spite of the fact that during the same time deaths from this cause for the state at large increased almost 100 per cent. Were it not for the irreducible minimum created by the constant admission of many almost hopeless cases of pellagrous insanity, there could now be little excuse for any considerable number of deaths from pellagra in this or any similar institution. Except under extremely reduced resources, its conspicuous presence in any community in which the diet is subject to regulation by central authority can no longer be justified.

There has been a rather sharp increase in the prevalence of pellagra during the past two years, but the increase in morbidity has been greater than that of mortality. A more general understanding of the proper treatment has made it possible to save an increasing number of patients who, under the old hit-or-miss methods, would have died. But this increased morbidity tells us in no uncertain terms that practical knowledge or means of its prevention have not been sufficiently diffused to enable the small cotton farmer or rural industrial worker to weather safely the dietary hazards occasioned by the recent shift in economic conditions.

Since it is people of restricted means who suffer most from pellagra—a situation which is aggravated by periods of economic depression—it has been said that to do away with this disease it will be necessary to reduce materially residual poverty and eliminate depressions. Both would, no doubt, be highly desirable, but fortunately neither is essential. There are numbers of nonpellagrous families in the pellagrous sections which, compared by the usual standards, are as poor as some of those who have pellagra or even poorer. Many of the inhabitants of the nearby southern Appalachian and Ozark sections, though in most respects notoriously poor, are seldom troubled with pellagra. It all depends on the source and nature of the food supplies and the ready availability of an adequate poverty-resistant and depression-proof diet.

The food situation in the rural sections of the cotton belt has become very sensitive to the price of cotton. The farms have gradually become less self-sustaining in the matter of both foodstuffs and forage as the production of cotton has become more intensified. The smaller, or tenant, cotton farmer has got into a rut from which he cannot easily extricate himself. Many have long since reached the point where they must depend wholly on outside assistance in making their crops, and the kind of crops produced is largely determined by those who extend the necessary aid. We must respect the right and propriety of the banker or merchant who furnishes the cash or supplies to designate, in the absence of other security, the kind of crops that shall be grown. A creditor cannot be expected to assume, to any considerable degree, the hazards incident to the production and marketing of major crops, other than cotton, under the conditions prevailing in this section. There are, however, in many localities public spirited bankers and country merchants who aid greatly in the various movements for better living by making the planting of a certain acreage in food and forage for home use a condition of every crop loan. Movements of this nature make most progress when the price of cotton is low.

However paradoxical it may seem, the slump in the price of cotton which operates to bring about an increase in the prevalence of pellagra will, if continued long enough, give rise to factors of a decidedly corrective nature. The more unprofitable cotton becomes and the longer it continues to be so, the greater will be the variety and abundance of food and forage crops grown in its stead, and the broader will be the basis for a more diversified diet. This very reaction was in evidence in many cotton-producing sections last year and has since become more pronounced and more general. This means a reduction of pellagra incidence in these areas, regardless of the severity and duration of the present depression. A similar favorable influence on the incidence of pellagra has long since been observed in those sections in which the devastating effects of the boll weevil have been such as to render the production of cotton uncertain and unprofitable.

It is not meant to imply that to control pellagra we must stop growing cotton. Cotton is the logical main crop in those portions of the South suited to its culture, and in all probability it will continue to be the backbone of Southern agriculture. But until the cotton grower has a wider and more dependable source of sustenance for himself and family than the few simple, nonperishable staples secured through the country store or commissary, pellagra will continue to exact its annual toll.

This brings us to the question of what there is to be done about it, and how it may be accomplished. To be permanently effective, corrective measures must be such as will offset the subtle influences which have progressively undermined the dietary stability of this section for a half century or more. In other words, endemic pellagra is largely a by-product of the more modern one-crop system of agriculture as practiced in the South. Its elimination will follow the adoption of a more diversified diet available at all seasons. This, in turn, must rest on either home production of a wider assortment of foods or a constant purchasing power covering a wider range. Nothing short of this can bring about a satisfactory solution of the problem.

Diversification of crops to a degree that will insure a more constant and adequate variety of home grown foodstuffs and sufficient forage and feed crops to maintain livestock and poultry for food purposes would seem to be the logical solution. From the point of view of both economics and health this has everything in its favor; yet the prospects of bringing about permanent diversification to this degree are anything but encouraging. Such a policy has long had the untiring support of the United States Department of Agriculture and the state agricultural colleges with their various extension services, and the loyal backing of the agricultural and lay press. Still, but little permanent headway appears to have been made. The going is comparatively easy so long as cotton is unprofitable, but the gains usually melt away as the price again advances.

It is the sudden and unanticipated shift from the higher to the lower economic level that pinches the diet most, and this period of readjustment to the more meager returns is almost invariably accompanied by a fresh supply of pellagra. If the price of medium staple cotton should become stabilized either at below 5 cents or above 15 cents per pound, the pellagra situation would largely take care of itself. At the lower level, the cotton farmer would soon be growing sufficient food for his requirements, while the higher price would enable him to procure a larger assortment of foods from outside sources.

Such broad movements as general diversification or price stabilization, or both, may eventually relieve the situation, but the possibility seems so remote that substitute or supplemental measures are urgently indicated. Specific and practicable knowledge aimed at the very root of this problem must be brought into play if a satisfactory measure of success is to be attained.

Pellagra is the first, and so far as we know the only, deficiency disease of urgent public health magnitude with which we have to contend in this country. It is brought about in an extraordinary manner in that it is produced by the *absence* of something. Measures somewhat foreign to the usual functions of a public health organization will therefore have to be employed in its control. We public health men have become an aggregation of seasoned germ fighters organized to function against positive disease-producing factors, and our machinery has not been fully geared to meet this new public health demand. Our ideas of preventive medicine have long been the destruction or elimination of vectors of disease, or the heading off of their effects by the employment of serums or vaccines. In dealing with a dietary deficiency disease, a program somewhat reversed and having as its object the restoration of a missing essential must become a more conspicuous feature of our armamentarium.

The extent and importance of this problem are clear. The factors concerned in its production are well known. The avenue of approach is wide open. We need not await the solution of the chemical problem as to the exact nature of the mechanism by which the absence of this specific food factor produces pellagra or its presence prevents it. In all probability, we shall eventually know more about the ultimate action of all the vitamins, but the chances are that this additional knowledge will add little to the means and methods for its prevention now at our disposal.

In approaching the problem of pellagra control, we will do well to bear in mind certain outstanding epidemiologic observations: Approximately 90 per cent of all cases of endemic pellagra have their onset during the period from April to July. Human experiments, as well as numerous observations in the field, have shown that it usually takes from three to five months for pellagra to develop after the diet has become sufficiently restricted. This means that it is during the late winter and early spring months that the foundation for the season's crop of pellagra is laid, and that it is toward the correction of this seasonal fault that the first remedial measures should be directed.

The most promising procedure would be the endeavor to bridge this gap by direct aid in coordinating and furthering the activities of existing agencies such as the agricultural, nutrition and home economics extension services and the various live-at-home and other movements having as their object the improvement of economic and dietetic conditions in the rural sections of the cotton belt. The aim should always be to assist these people to solve this problem by their own industry and resources. Progress will be slow, but whatever is accomplished will be permanent. Subsidies in food production and distribution will produce results, but this can be neither accomplished nor perpetuated without outside financial assistance.

The Public Health Service has for some time been engaged in the study of the relative pellagra-preventive value of the more common staple foods and foodstuffs. Early in this study, fresh lean meats and milk were found to be dependable pellagra preventives, but they are not within reach of the average pellagrous household. Here and there a family may be induced to establish a dependable source of one or both of these, but on the whole little progress may be expected if sole dependence is placed on their introduction in adequate amounts. With this limitation in mind, attention has more recently been centered on those foods or foodstuffs which may be most easily and cheaply produced at home or otherwise made available at the season when pellagra-preventive foods are normally scarcest. Other things being equal, those which require the least effort to produce or prepare for the table and will best fit into the established system of agriculture and the domestic habits and customs of these people will prove most practicable.

So far, thirty-five foodstuffs have been tested. Of these milk (including buttermilk and canned evaporated and dried milk), fresh beef, canned corned beef, liver, canned salmon, canned haddock, tomatoes, turnip greens and canned English peas have each been found to prevent pellagra when added in sufficient quantity to an otherwise pellagra-producing diet. Dried beans and peas, eggs, canned spinach, green cabbage and canned string beans, though less effective, are valuable contributory sources of the pellagra-preventive factor. Cornmeal, wheat flour, rye flour, oatmeal, molasses, cane syrup, sweet potatoes, mature onions, carrots, rutabagas, salt pork, lard, cottonseed oil, butter and gelatin have little or no pellagra-preventive value, regardless of the quantity used. Dried yeast and commercial wheat germ, although not commonly looked on as human foods, are good sources of the pellagra-preventive vitamin and are valuable supplements, especially as temporary expedients under emergency conditions. A study of collard, kale and mustard greens is now in progress, with indications that the collard greens, at least, will prove to be of value.

One does not have to look far to see that during the early portion of each year the diet of many people of the pellagrous sections is limited almost exclusively to the class of foods which have been found to be nonpreventive. Although poor protection against pellagra, foods of this nature are nevertheless essential. They serve as the basis for sound nutrition and, when properly supplemented, constitute a satisfactory ration. Their use should not be discouraged. The goal to be sought is amply exemplified in every pellagrous community. In looking for cases of pellagra, the home surrounded by evidence of a good garden, or a cow or two, a few pigs and some poultry may as well be passed up, for the chances are less than one in a thousand that pellagra will be found. On the other hand, the home surrounded only by last year's cotton patch will always bear watching.

MUCIN THERAPY FOR PEPTIC ULCER

PRELIMINARY REPORT OF OBJECTIVE RESULTS ON PATIENTS WITH INTRACTABLE ULCER

CLARENCE F. G. BROWN, M.D.
STUART P. CROMER, M.A.
EDWARD L. JENKINSON, M.D.
AND
N. CLARK GILBERT, M.D.
CHICAGO

Fogelson[1] reported successful results in the treatment of peptic ulcer with gastric mucin. Kim and Ivy,[2] and Fauley[3] performed experiments on animals and reported that mucin prevented ulcer formation in dogs with biliary fistulas. Alkalis were found by Kim and Ivy[4] to prevent ulcer formation, but the animals did not do well in general.

The results of these workers seemed to justify an independent clinical study. Atkinson[5] reported that mucin therapy was successful in ulcer-bearing individuals.

In the past it has been impracticable to estimate the value of ulcer management because of the difficulty of proper control and the use of subjective evidence.

Cases of peptic ulcer present such diverse clinical courses that most of them cannot be used for the purpose of passing judgment in regard to the value of a certain management. Previous experience at St. Luke's Hospital clinic showed that many ulcer patients recovered without any form of management, while others improved with a favorable change in environment, a few dietary suggestions, powders, belladonna, bromides or phenobarbital. A small percentage persisted in having difficulty on strict managements.

METHOD OF EXPERIMENT

As a control procedure, patients were chosen for mucin therapy who had experienced many recurrences and who had failed to improve on hourly feedings and hourly powders. An additional control series of "difficult" patients was continued on feedings and powders.

Subjective evidence has been overemphasized in estimating the healing of peptic ulcer. Frequently we have seen ulcer defects grow deeper or additional ones appear on various managements considered adequate, when the patient was subjectively improving and even entirely free of distress. Conversely, in other patients, the defects in topography diminished or disappeared and the subjective symptoms became more severe. The degree of distress, its location and behavior varies greatly in different patients, even in the same patient at different times if he is observed critically. Some of our most difficult ulcer patients had a minimum of distress, especially those prone to ooze a good deal of blood into the stomach. Subjectively these were easily palliated. Some of the patients objectively controlled with little difficulty had the most persistent subjective complaints. We believe, however, that we have not included the psychalgias in the present series because of the strict diagnostic requirements. Further knowledge of the rôle of the vegetative nervous system may explain these observations and perhaps at some future time an investigator or clinician may be able to rely on subjective evidence in peptic ulcer. For these reasons, objective data were obtained in the patients studied. The objective criteria to which we refer are the presence of blood in the stomach and stools, hyperacidity, and definite roentgenographic observations.

A definite diagnosis was thought essential in this study although, in general, relatively few ulcer patients can qualify in all respects. The following conditions were required for every patient: an unimpeachable ulcer history; occult or gross blood in the stomach and stools; hyperacidity; relief of distress with mucin, powders, neutralizing food or aspiration, and definite roentgenographic evidence.

One hundred and sixteen ulcer patients have been treated with gastric mucin; the present report includes thirty-seven cases. The smaller number was chosen because they had been intractable over a long period on strict management. The remainder either had not been observed for a sufficient length of time or failed to report regularly for their weekly tests.

Twenty-one patients were studied in the hospital. Many of these patients had been under our care on various ulcer managements for years. The average time spent by each patient was 35 days; a total of 735 hospital days. The hospital period was made as long as was financially possible to obtain objective evidence and exercise clinical control. Before entrance, roentgen studies, gastric analyses and stool examinations were made and the patient placed on hourly "neutralizing" feedings for an average of ten days. Motor meals were given when indicated. No mucin was administered until sufficient control determinations had been made and clinical behavior noted. Each patient, except those having gross hemorrhages or showing signs of perforation, underwent the following routine: a weekly forty-five minute Ewald test meal; a weekly two hour fractional meal, followed by from two to six hour periods of from fifteen to thirty minute aspirations to study secretagogue characteristics of various mucins and alkalis. Aspirations were done twice weekly before breakfast and twice weekly at 11 p. m. Weekly blood counts were taken. All stools were analyzed. The patients were studied with roentgen rays at periods of from two to four weeks. When showing occult blood in the stomach contents or stools the patients were kept in bed, but they were allowed to be up and about after none was found. On dismissal from the hospital they followed the outpatient routine.

[5] Atkinson, A. J.: Gastric Mucin in the Treatment of Peptic Ulcer, J. A. M. A. **98:** 1153-1156 (April 2) 1932.

Sixteen of the thirty-seven patients were diagnosed, observed and treated exclusively as outpatients. The patient was questioned and examined every week. All, including the twenty-one former hospital patients, had Ewald test meals and stool examinations at each visit. Blood counts, fractional test meals, motor meals and roentgen examinations were continued in the combined group when indicated.

The average observation period in this group thus far has been slightly less than one year.

The average duration of ulcer symptoms for the group of thirty-seven was seven years and nine months per patient. There was an average of sixteen recurrences per person. Previous hospitalization totaled 2,171 days, giving an average of 58 days per patient.

When mucin was begun, strict ulcer management had been given to each patient for an average time of three years and six months.

The age average of the group was 31 years and 6 months.

Thirty-one were men, six were women. Thirty-three had duodenal ulcers, two jejunal ulcers, one a gastric ulcer, and one had both duodenal and gastric ulcers. Of these ulcers, fourteen were of the penetrating type. Three patients had massive hemorrhages when they came under our care, and eight had histories of repeated hemorrhages. Five had histories of perforation.

The majority of the patients used manifested no other disease conditions which in any way related to the ulcer. The Wassermann test was taken on each person in this series.

RESULTS

The positive benzidine reactions in the stomach contents disappeared on an average in nine days, the longest time being twenty-six days. In the control series on hourly feedings and alkalis, the benzidine reaction became negative on an average in twenty-four days. Several in the control series were not included in this average, because they never became negative on the usual management prior to the administration of mucin.

The positive benzidine tests in the stools became negative on an average of 11.5 days after starting mucin. The control series became occult blood free in 27.2 days.

The average gain of weight of the mucin treated patients was 13½ pounds (6 Kg.); the average for the control series was 9 pounds (4 Kg.).

As the mucin treatment progressed, a study of gastric acidity showed that in a majority of patients the readings in the free hydrochloric acid decreased as judged by the weekly Ewald test meals. Some remained stationary, and a few went up during the first twelve weeks of the treatment. In the latter group, double doses of mucin were used for intervals of from three to five weeks. This lowered the free acidity determinations on an average of from 15 to 20 units, but when the ordinary doses were resumed the acidities again increased to the progressively diminishing original levels. The control series on powders and feedings also maintained a high acidity; a few diminished slightly, but the majority remained at the original level or went higher as the treatment progressed.

No management thus far used in our clinic has succeeded in transforming hyperacidity to a so-called normal acidity without the "healing" of the ulcer or the relief of the retention. As the ulcer "heals," the hyperacidity usually decreases unless alkalis are used. In a minority of ulcer patients, managed with alkalis, the free acidity diminished; but in the majority, the acidity increases during the ulcer healing process. Whether or not the ulcer heals, the chronic ulcer patient tends to maintain a hyperacidity. Mucin therapy has lowered the acid levels of healing ulcers in intractable patients more effectively than any method we have previously employed. It is to be kept in mind that these statements are based on data obtained by morning test meal aspirations rather than 11 p. m. aspirations.

The hypersecretion accompanying peptic ulcer was moderated more with mucin therapy than with the same management with alkalis. Alkalis seemed to diminish a hyperacidity and hypersecretion for several weeks and apparently overcame this troublesome complication entirely in easily controlled ulcer patients. In the intractable patients, the hypersecretion increased after several weeks for some unknown reason. This was more marked with alkalis than with mucin.

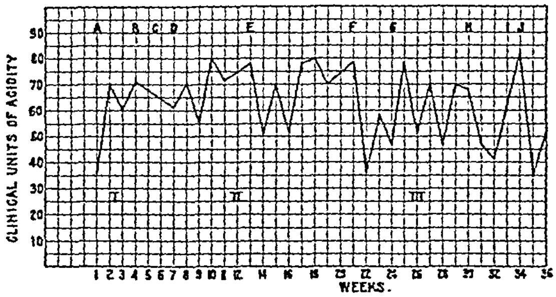

Chart 1.—Gastric free acidity levels; results of weekly Ewald test meals. The behavior of the gastric free acidity is shown in a typical intractable "peptic ulcer." The patient was a Negro porter, aged 44, who had had a recurring duodenal ulcer for eleven years. The previous hospitalization for ulcer management was 112 days. Since the ulcer was first diagnosed, he had received frequent feedings and alkaline powders. He began treatment in our clinic in 1928. At this time, roentgen studies showed a definitely deformed duodenal bulb with a residue at the end of five hours. Hourly feedings and powders were used until 1931. The distress, in spite of the strict management, had become progressively more severe and attacks more frequent. He had had night distress for five years. Vomiting had been his only means of complete relief. There was a total disability for eight months before mucin was begun. He became free from distress on the first week of mucin therapy. The stomach contents and stools, which had remained strongly benzidine positive with the alkaline management, became negative after one week of mucin and have remained so. He returned to work two months after starting mucin. There has been no recurrence since the mucin treatment was started.

A, hourly feedings and hourly powders were started as the patient entered the hospital. *B*, the patient had very little relief from distress but was released from the hospital. *C*, the patient stated that he was so weak and distressed that he was unable to come to the clinic for three weeks. During this time he took hourly feedings but no powders. *D*, hourly feedings and powders were resumed with unsatisfactory subjective relief. *E*, alkaline powders were stopped. A tablespoonful of mucin was given every two hours; the hourly feedings continued. *F*, the dosage of mucin was doubled to see whether hyperacidity would diminish. *G*, the ordinary dose of mucin was resumed. *H*, mucin again was doubled. *I*, the patient ate sardines and had nausea, vomiting, diarrhea, and generalized abdominal distress. He did not come to the clinic and went without mucin for one week. *J*, a double dose of mucin was resumed. The roman numerals refer to the roentgen observations made by E. L. Jenkinson. I, duodenal bulb deformed on both curvatures; one fifth of the barium remained at the end of five hours. II, duodenal bulb was deformed and fixed, having a clover leaf deformity; there was still a small residue at the end of five hours. III, duodenal bulb showed definite improvement since the former examination, as there was less deformity. There was still a residue at the end of five hours.

Hourly feedings, without the hourly alkaline powders, when used on easily controlled ulcers, had approximately the same effect as mucin therapy in diminishing a hypersecretion or hyperacidity.

When an ordinary dose of mucin, which is a rounded tablespoonful (15 Gm.), was placed in the stomach at the end of a two hour fractional test meal there was usually a slight increase in free acidity. This was sometimes just under or just over the maximum reached at the peak of the test meal and usually diminished after from thirty to sixty minutes and was followed by a gradual fall, which was maintained until the end of the test, from four to seven hours later. The secretion rate, with and without mucin, was checked in fifteen all-day experiments of this type. The average did not exceed that obtained on a similar series of ulcer patients aspirated at from fifteen to thirty minute intervals, who had received either no mucin or some combination of alkali. Therefore, no marked secretogogue effect was obtained from the mucin preparation we used. However, Rivers,[6] has obtained from some mucin a decided secretogogue action, which we are informed is now being controlled by both chemical and biologic assay.

Roentgenograms were made and fluoroscopy was performed on all patients at intervals of from two to four weeks. A progressive improvement resulted in a majority of the patients. The hourly feeding series and the hourly feeding and hourly alkaline powder series also showed improvement. In the thirty-seven intractable ulcer patients, in whom further improvement on strict ulcer management was not noticeable, it was possible to influence the roentgen manifestations in a majority of instances in a favorable manner by the use of mucin. A decrease was evident in the deformity of the topography of the bulb or stomach when studied at a time of maximum activity and maximum filling. Several patients improved roentgenographically up to a certain point but failed to improve further, owing perhaps to the existence of scar tissue. Most of the patients with a penetrating type of peptic ulcer showed a progressively diminishing defect which accompanied the disappearance of blood from the stomach and stools, and the decrease of acidity and subjective relief. This leads us to believe that these ulcer craters "healed" with mucin therapy when they had failed to heal with similar diet and alkalis.

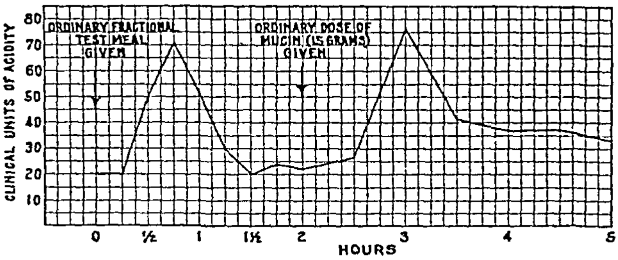

Chart 2.—A comparison of the acid stimulating property of mucin with that of a bland gruel. This patient is being treated for a duodenal ulcer of penetrating type.

In the thirty-six out of thirty-seven intractable ulcer patients, mucin gave subjective relief of distress in an average of eight days per patient.

There was one failure in the series. The diagnosis was a penetrating type of duodenal ulcer and multiple diverticulitis. The patient was not benefited by hourly feedings and alkalis and received no relief or objective improvement from mucin. Each was tried for four weeks. Morphine in large doses was palliative only. It was felt that surgical aid was indicated. When the abdomen was opened, a large red granulomatous mass, in the region of the first part of the duodenum, was found. This apparently surrounded a penetrating ulcer. The patient obtained partial relief from a posterior gastro-enterostomy, followed by milk and cream and alkalis. Six weeks later mucin was started again, with complete relief on the first day. Normal acidity and benzidine negative stools soon followed. We assume that perhaps it took that long for the granuloma to subside and the enterostomy to function smoothly.

SUMMARY AND CONCLUSIONS

1. Thirty-six out of thirty-seven patients who had partial to complete disability on previous strict ulcer management have been relieved objectively and subjectively by mucin.

2. Roentgen deformities in topography were influenced more by administration of mucin than by former management.

3. Emptying time or retention was diminished on mucin treatment. We do not consider that we have sufficient evidence to make a comparative statement at this time.

4. Disappearance of gross and occult blood in stomach and stools was more rapid with mucin treatment than with conventional management.

5. Mucin treatment was effective in controlling several massive hemorrhages from the stomach. Other methods were also effective.

6. There have been no recurrences in thirty-six patients who had frequent previous recurrences.

7. Hyperacidity, as measured by weekly Ewald test meals, was not lowered on the treatment of hourly feedings and powders and was only somewhat lowered by mucin treatment. All the patients were taken off powders or mucin and food twelve hours previous to the test meal.

8. Mucin in ordinary doses did not lower gastric acidity appreciably when placed in the stomach after a two hour fractional meal followed by aspirations at frequent intervals for from four to seven hours. In the mucin we used we did not observe any secretogogue action which interfered with the beneficial effect. From our objective observations, the therapeutic effect is due to some factor other than neutralization of acid. The quality of commercial mucin has been improving, as the result of the cooperation of the makers with Drs. Ivy and Fogelson. A histamine-like substance is no doubt present in varying quantities, as it is present in other tissue extracts, such as liver extract. This is now controlled by chemical and biologic assay. We have seen no toxemias. There has been a notable increase in the feeling of well being and an improvement in the appearance and behavior of the mucin-treated patients.

9. Mucin has a beneficial effect on the bowel.

10. There was one failure; at operation a red granulomatous tumor mass was found having formed about an ulcer of penetrating type. Gastro-enterostomy was done. Distress persisted with alkalis for six weeks and then subsided with mucin; this may have been due, of course, to functional improvement of enterostomy at this time.

11. We have found in the past that a majority of peptic ulcers heal with no treatment or any treatment. The minority are sometimes very resistant to the best forms of management. Mucin has helped these intractable cases. We realize that any local palliative treatment does not in itself change the constitution or the vegetative nervous system of the patient who is an ulcer-bearing individual. We shall persist in this comparative investigation of methods in the hope that further physiologic studies will disclose more clearly the etiology and treatment of ulcer.

INEXPERT REFRACTION

JOHN GREEN, Jr., M.D.
AND
CARL BEISBARTH, M.D.
ST. LOUIS

The eye is defined very simply as "the organ of vision" (Century Dictionary, p. 2103). A number of secondary definitions are given, merely amplifying or extending the first.

Is it presumptuous to begin a paper to be presented before the most representative group of American ophthalmologists with a statement so axiomatic? If so, we crave forgiveness. Recalling our undergraduate years and those immediately following, when we were first putting to practical use the concepts of medicine and surgery acquired in the laboratories and clinics, that which preeminently claimed our interest and attention was the means of restoring the sick patient to health. We were aware that a malady might, through the creation of toxic products, seriously interfere with the normal activities of certain organs, e. g., the impaired function of the kidney in scarlet fever or the development of myocardial changes in the course of diphtheria. Therapeutic indications were clear; to rid the body of toxins as speedily as possible and to lighten the load on impaired organs. The restoration of function was incidental to the procedures employed to restore the patient to health. Sometimes the cure demanded the destruction or removal of organs, e. g., the abscessed tooth, the tuberculous kidney, the hypertrophied prostate, etc.

Impairment of the function of a bodily organ is due to (*a*) toxins incident to some general malady, (*b*) toxins generated by infection in some distant organ or (*c*) disease or growths originating in the organ itself.

Impairment of the function of the organs of special sense may be wholly independent of local or general disease. The senses of smell and taste are subject to fairly wide variations, and may be made more acute by training, as in the case of wine and tea tasters. Hearing may be impaired by occlusion of the external auditory canal with wax. The sense of touch may be diminished by cold or conversely increased by moderate heat. The delicate and accurate tactile sense of the blind has been developed by constant manipulation of objects to determine their nature in the absence of visual perception, and the necessity of learning to read the raised types.

Above all, the sense of sight is capable of improvement by the simple expedient of placing a lens before the eye. It is not at all necessary that both the elements, axial ametropia and astigmatism, which are inherent in most eyes, be considered in the composition of a lens that is intended merely to improve vision; for this purpose usually a simple plus or minus sphere will suffice. Some are content with this improvement, and not requiring high visual acuity, having no symptoms of eyestrain and not possessing delicately poised nervous systems, do not suffer the miseries of asthenopia. For others—and their name is legion—the most exactly estimated compound lens, with both spherical and cylindric elements determined to the eighth of a diopter and the axis of the cylinder exactly placed, is a necessity if the eye is to see most acutely and function most comfortably.

The young student of ophthalmology will make an auspicious beginning if, either through correct teaching or the exercise of his native intelligence, he has indelibly impressed on his mind the fact that the eye is "the organ of vision," and that the work to which he is about to dedicate his life has three simple (but tremendously important) objects, namely, the preservation and increase of vision, the comfortable functioning of the eyes and the prevention of blindness.

The majority of all patients who consult the ophthalmologist have, primarily at least, errors in refraction. Certain external disorders, e. g., blepharitis, conjunctival hyperemia and hordeolum are frequently dependent on uncorrected ametropia. Congestion of the choroid (the "fluffy choroid" of Risley) and the veiling of the papillary margins in hyperopia or hyperopic astigmatism are not, in our opinion, imaginary concepts. Who has not seen the disappearance of such signs after the wearing of an exact correction? If further proof were needed of improvement in the intraocular circulation, hence of the nutrition of the retina, one has only to recall the often striking increase in visual acuity following the constant wearing of appropriate spectacles.

One should not fall into the error of regretting the appearance in one's office of "just another refraction case." It is our conviction that such an attitude of reluctant tolerance is at the bottom of much of the mediocre work that is, even today, being done in this all important branch. Rightly viewed, the patient with ametropia and all the symptoms incident thereto presents to the ophthalmologist a challenge which is to be met enthusiastically with all the care, time and painstaking effort that would, without second thought, be bestowed on the patient who is a candidate for an operation for cataract.

It has been our practice for many years to secure from the patient a complete history of his previous contacts with opticians, optometrists and ophthalmologists, and we take pains to dispel the confusion that usually exists as to which type of examiner he has consulted. Careful inquiry is made as to the use of "drops"; the duration of the symptoms of cycloplegia giving a hint as to whether homatropine, scopolamine or atropine has been used; the time that has elapsed between the cycloplegic and postcycloplegic tests; the number of postcycloplegic tests (if more than one); the method of securing glasses; whether or not an examination has been made of the finished product; whether there has been insistence on a spectacle mounting, rather than an eyeglass; whether specific instructions have been given as to the period of wearing the glasses—constant, inconstant or for near vision only, or whether a return visit at the end of a fixed period was suggested.

We endeavor, also, to secure some notion as to whether any tests of the ocular muscles have been made, but we must confess that, in most cases, the patient's recollection of the details of such tests (even when the subject is introduced by leading questions) is too hazy to serve as reliable evidence.

We have discussed with many colleagues their attitude toward eye testing. Is the task enjoyable or irksome? We have observed, so far as possible, the methods employed by other men; we have tried to determine whether the older men have modified their methods of objective and subjective examination in the light of recent advances in technic; we have scrutinized our own methods and from time to time have made

[illegible] Medical College

modifications, some of which have served as checks on prior methods and have been retained.

As a result of these inquiries and observations, we have reached certain conclusions which seem to offer an explanation for some of the inexpert refraction that, from time to time, comes to the attention of every ophthalmologist.

REASONS FOR INEXPERT REFRACTION

1. There is the ophthalmologist who is "not interested in refraction." Is not this almost tantamount to a declaration that he is "not interested in ophthalmology"? If ophthalmology has any attraction for him, it lies in diagnosis, therapeutics and operations. Closer inquiry will usually reveal the fact that he has received just enough insight into ophthalmology to realize that refraction tests require precious time that might be more lucratively employed. It is our positive conviction that this type of practitioner is far less frequent now than he was twenty years ago, and it is to be hoped that he will eventually become as extinct as the "dodo."

2. Some ophthalmologists have so many "irons in the fire" that they have "no time for refraction." The demands of teaching, the pursuit of original research, the writing of papers, the attendance at engagements outside of professional life and the exigencies of private and consultative practice (which may include otorhinolaryngology) render it physically impossible to "do refraction" (there simply are not enough hours in the day). Therefore this part of the practice is delegated to a medical assistant. This may be unfortunate for the latter, who is notoriously apt to fall into the ways and adopt the ophthalmologic habits and concepts of his chief. In such circumstances it is not surprising that the young man soon comes to regard his job as irksome and hopes for an early release from its drudgery. We wish, however, to state that we know of many offices in which this arrangement works well, but only because the chief is interested and is an expert in refraction and insists, at least in the beginning, in supervising the work of the assistant, and later when the latter becomes more expert is ever willing to offer counsel and advice.

In lieu of a medical assistant, an ophthalmic technician—usually a recent graduate from a woman's college—can be trained to serve a very useful purpose in the preliminary tests; but there should, invariably, be a check-up and revision by the ophthalmologist, as the patient should have the benefit of his mature judgment in writing the prescription, and his opinion is necessary to determine the presence or absence of extra-ocular or intra-ocular disease.

3. The attitude that "the game is not worth the candle" is held by some ophthalmologists. We are quite sure that there are some colleagues who view with a smile of amused tolerance what they regard as excessive concern for the refinements and niceties of eye testing. They point out that the enthusiast's most meticulous efforts may be quickly nullified by the bent frame, or the round lenses turned to an axis not intended. They recite with glee the easy tolerance of some eyes "fitted?" with lenses unsuited either in spherical or cylindric component. But they seem to forget that for one pair of eyes so tolerant there are dozens that would be tortured by such maladjustment. Much depends on who is the owner of the astigmatic off-axis eyes.

4. Some men practicing in smaller communities have stated to us *that they feel themselves in direct competition with optometrists.* To maintain their standing with patients they think they are compelled to "speed up" the work of refraction, to adopt short cuts, to get the patient through in a day, etc., in a word, to lower the quality of the work to optometric levels. Such a practice seems to us sheer folly, and its continuance constitutes a betrayal of professional integrity. By method and practice the ophthalmologist should secure the most accurate measurement, and it is a matter of no moment whether his result is attained in one day or ten. If the ophthalmologist is going to fall to optometric levels, he is doing far more than optometric propaganda could ever do to perpetuate in the public mind the utter confusion that now prevails.

5. Much inexact refraction emanates from eye clinics. Many of the clinics are undermanned, and the number of patients demanding refraction exceeds the number that can be tested accurately, so the policy of "roughing it out and letting it go at that" prevails. *Happily, this criticism does not hold for some clinics in* which the technical equipment is of the best and one or more men, skilled in refraction, are paid for doing expert work.

The beginner in ophthalmology should adhere strictly to the teachings and practices of the art and science of refraction laid down by our ophthalmologic masters. Such a course may not in the beginning bring to him a large clientele, but in the long run he will secure the confidence of the public, or at least, that part of the public that is sufficiently discriminating. In the meantime, he will have the consciousness of having done his work with precision and thus upheld the highest ideals of professional practice.

VARIATIONS IN REFRACTION

It is well always to be on guard against misjudging the work of a colleague who may have preceded one by several years in testing the eyes of the new patient. His correction, as determined by neutralization or by one of the lens-measuring devices, may seem surprisingly at variance with the determination of the present refraction, and one may be tempted to disparage his skill. An ophthalmologist who has been long in practice will have had many experiences of the changes in the refraction of the human eye retested several times over a period of years; at times the change may be so striking that he may have misgivings as to the accuracy of his own prior tests. Experiences of this sort breed humility and suggest extreme caution in condemning the correction of a predecessor known to be a careful and painstaking examiner. We know that some of our patients, for whom we have spared neither time nor pains in deciding on the most adequate correction, have deserted us for colleagues who, on subsequent retesting some years later, have been astonished at what appeared to be the inexactness of our estimation. An increase or decrease in hyperopia, an increase or slight decrease in myopia, a variation in the degree of astigmatism and a shifting of the axis are common changes which may and often do occur in the space of a few years. Such changes are well known to patients who come at stated intervals to be "checked up" even in the absence of symptoms. Others wait until symptoms obtrude unpleasantly to remind them that "it is time to have my glasses changed."

When all due allowance has been made for variations in refraction which normally occur with the lapse of years, there remains a large group in which by no stretch of the imagination can one bring oneself to believe that the prior estimate was correct or even approximately so. We have seen—doubtless an experience shared with many members of this Section—persons with hyperopia supplied with minus spheres, those with hyperopic astigmatism given minus cylinders, those with mixed astigmatism treated as if they had the myopic variety. A common error is the prescribing of spheres for patients with compound hyperopic astigmatism.

In the management of presbyopia there is much unwisdom manifest. Failure to take into consideration the reading habits of the patient, the distance at which he prefers to hold his book, accounts for improper presbyopic additions. Occupation must be considered; great care should be taken to adapt the near vision lens to the distance habitually required in the occupation. The piano and bridge player need special consideration; the double bass player in the orchestra must, perforce, view his music at double or more than the usual reading range. The amount of accommodation remaining in presbyopic eyes is not always equal; if found unequal, tests should be made to determine whether dissimilar reading additions will not prove more comfortable.

Far too little attention is paid to the estimation of the precise refraction in eyes with corneal deformities and opacities, in eyes with chronic glaucoma and in eyes with early cataract. Painstaking, prolonged and repeated tests will often yield results surprising to the examiner, and immensely gratifying to the patient—results not predictable on the basis of the known pathologic process in the eye. There is no more fascinating game (to the enthusiast in refraction more stimulating than bridge or cross-word puzzles) than the contest with the patient to provide him with the ultimate in vision-improving glasses. We have used the term "contest" advisedly. Given an unintelligent, unresponsive patient, one who has never been trained to make accurate observations, who tires easily or who is openly antagonistic, and it is a game that should arouse in the examiner the well known American competitive spirit. As in other games, the examiner may find himself defeated, but if he has made a valiant effort to do his best he will go down with colors flying, and undiscouraged, will be ready and eager to repeat his efforts on the next patient.

With the advance of cataract, the hyperopic eye loses its hyperopia or becomes myopic in varying degrees. It has been our experience that many examiners—and this statement applies to ophthalmologists as well as optometrists—are content to sharpen distance vision by prescribing minus spheres and wholly disregard the associated astigmatism. This practice often leads to overcorrection of the myopia, the examiner piling on all the minus spheres possible in an effort to secure better acuity; usually a spherocylindric combination, which measures the true refractive state, implies a weaker sphere. It has been our experience that as a rule, a lens representing the true refraction of such eyes is gratefully accepted. With advancing cataract, the astigmatism may change rapidly in amount and axis; such eyes, therefore, require frequent retests. On the other hand, some of our patients with early cataract rebel against the spherocylindric combination which yields the highest acuity and insist that a plain sphere is more comfortable.

The patient with beginning cataract is even more interested in securing a reading lens that will promote him from being a reader of "headlines only" to ability to read ordinary newspaper or magazine print. To attain this end the greatest care must be taken to determine the exact cylinder (and precise axis), and sometimes it will be found that the best axis of the cylinder for reading purposes does not coincide with that which has been determined at 6 meters. Even if the cataract is so far advanced that an acuity better than 6/30 is not secured and it is found that plus additions do not enable the patient to read better than J. 5 or 6, the best combination can be incorporated in a Zeiss telescopic spectacle; thus reading vision may often be raised to J. 1.

We have no apologies to make for stressing the importance of securing the most accurate correction in eyes with early cataract or quiescent glaucoma. The best interest of a very old and decrepit person is not always served by performing a surgical operation of any sort, and there may be any number of cogent reasons for avoiding, or at least postponing, operation. In the meantime, it is our duty to afford as much comfort and solace as possible by giving all possible optical aid.

METHODS OF EYE TESTING

In recent years comparatively few papers have dealt with the consecutive steps in eye testing, leading to a determination of the lens to be prescribed. (A notable exception is the excellent paper by Bahn.[1]) The adoption of a definite routine, permitting of variations, to suit the exigencies of unusual conditions, seems to us a necessity. Not all examiners will be satisfied or successful with a set formula; it is far better that each should develop a method which, while conforming to the principles of physiologic optics, yields a large measure of satisfaction to himself and comfort to his patient.

Our own method is a composite of several well known procedures and was adopted with a view to providing all necessary checks. It is a great satisfaction to reach identical conclusions as to the strength and axis of the cylindric component using (*a*) the astigmatic dial and cross-lines and (*b*) the cross-cylinder.

First, a word as to equipment. It is vitally necessary that one's test lenses should measure, both singly and in combination, the refractive power of the finished lens as it comes from the optician. Various manufacturing opticians are now supplying Vertex refraction test lenses which conform to the requirements just stated. Jackson[2] and others have pointed out the advantages of planospheres and planocylinders.

The trial frame should be comfortable, capable of independent lateral movements of each cell, with protractor scale accurately etched on each rim. We consider it advisable that the milled head which rotates the revolving cell containing the cylinder should be large and accessible so that the patient himself may twirl the screw at certain stages of the test. The refraction corridor should be dark or at least in half light. An excellent arrangement is that described by Olsho.[3] The test letters are in a four-sided box, with central illumination evenly diffused by reflection from mirrors lining the four walls. In addition to the test card—we prefer the Thorington chart with letters subtending an angle of 4 minutes—we have astigmatic charts, both radiating lines and rotatable

cross-lines, and the little Maltese crosses (in three sizes) which Beach[4] devised as an aid to the detection and measurement of astigmatism. Our astigmatic charts are based on Lancaster's[5] charts. We have had a draughtsman draw, in india ink, on the finest of white cardboard, radiating lines 3 mm. in width, at intervals of 10 degrees. To economize space, this chart is shaped like an old-fashioned fan, the lowest radii being extensions, respectively, of the 10 and the 170 degree line. The cross-lines 4 mm. in width are drawn on a circular disk which can be rotated around a pivot at the center. Occasionally we use Friedenwald's[6] charts—black lines bordered by white on a gray background—and find them useful with some patients. Our ranges are 6 meters = 20 feet.

The preliminary examination is made with the greatest care. We believe that none of the tests should be performed perfunctorily. After noting the visual acuity without glass, the patient is greatly overfogged—to a point where vision is not more than 6/80. The lights illuminating the test letters are turned off. The patient is requested to look vaguely in the direction of the test cabinet, now in semidarkness. He is instructed to make no effort to see clearly. After waiting several minutes, the examiner begins to "lift the fog" by turning on the lights illuminating the test charts. The patient is urged to read all he possibly can and is given time to decipher some of the letters on the line below the one he states he can clearly see. A certain amount of levity is permissible in the effort of the examiner "to sell" the fogged line of letters to the patient. We have found it useful to offer a fictitious prize, the more incongruous the better, e. g., "a big cigar" to the women, or "a powder puff" to the men, in an effort to amuse and awaken interest in the test. For other patients a serious explanation, with an appeal for all possible concentration on the matter in hand, serves the purpose better. In testing children it is necessary to proceed slowly, to gain their confidence, to discuss their dolls or their pets, to enlist the active help of the mother in pointing out the letters or symbols, and in every way trying to metamorphose your activities and the child's into a game. Therein lies the value of interesting pictures—we use Ewing's pictographs (cross, pitcher, ring, square, chair, star, etc.)—which we find originally more interesting to children than the "E" card, and are eagerly asked for at the reappearance of the child for the cycloplegic test. The acuity of the very youngest children is better secured, perhaps, by the use of the "E" card because it is not necessary for the child to name the symbol, but merely to designate its position by positions of the hands. For such children the refinements of subjective testing are out of the question; it is best to rely on a correction based on careful and repeated skiascopy. But for the child of 5 to 8, our skiascopic findings are always supplemented by a subjective test which can often be made with surprising accuracy.

In older children and adults we try to secure intimations of the existence (or nonexistence) of astigatism by the observation of the fan chart while the patient is still under a fair amount of fog. At this point we confirm these intimations by the use of the cross-cylinder, and endeavor to secure a spherocylindric combination which yields not better than 6/10 vision, and which makes the cross-lines of the astigmatic chart appear "matched" (not in sharpness of outline, but having "an equal degree of blur"). Reduction of the sphere will now increase acuity and the cross-cylinder is again used to determine whether an increase or decrease in the cylinder is required. The cross-cylinder is now used (method of Jackson,[7] modified by Crisp[8]) to determine the precise axis. As a final check-up we make the round of the trial case with 0.12 D. spheres and cylinders. Having felt the need for greater refinement than is afforded by the use of the 0.12 D. cross-cylinder, we have had ground a cross-cylinder consisting of a —0.06 D. sphere on one side and a + 0.12 D. cylinder on the other. Given a low astigmatism, which has been perfectly corrected, an observant patient can detect no difference in the sharpness of the smallest letters in the two positions of the cylinder, but one cross-line of the astigmatic cross will be found to be better defined when the plus axis of this very weak cross-cylinder is parallel with the plus axis of the cylinder in the frame, and the other cross-line will be sharper with the cross-cylinder turned 90 degrees.

THE TEST UNDER CYCLOPLEGIA

The skiascopic estimate is placed on the patient, and the acuity noted. A weak sphere, either plus or minus, that improves vision, indicates whether the sphere in the trial frame is to be changed. The axis of the cylinder is determined by the cross-cylinder. The strength of the cylinder is also determined by the cross-cylinder. When vision has reached 6/7.5 +, the cross-lines (modified Lancaster chart or Friedenwald's chart) are displayed, with one axis corresponding to the position of the cylinder axis in the trial frame. The 0.12 cross-cylinder is used in the two positions. If there is a reversal in the distinctness of the cross-lines with a reversal of the 0.12 cylinder, it is an indication that the cylindric component is correct to less than 0.25 D. The sphere is reduced to yield 6/6 or 6/6 + acuity. The 0.06 cross-cylinder is used as before and the cylinder allowed to remain as it is in case of reversal in distinctness of lines, or changed in accordance with the indications of the cross-cylinder. Finally, the axis is redetermined by using the 0.25 or occasionally the 0.50 cross-cylinder.

There are some patients who experience difficulty in detecting the minute differences in lines and letters when the 0.12 and 0.06 cross-cylinders are used; under these circumstances we have found clear intimations by having the patient observe the smallest of Beach's Maltese crosses with these weak cylinders held in the two positions.

The postcycloplegic test is begun by placing the correction found under cycloplegia in the trial frame and making such modifications as may be necessary. The astigmatism is determined both by the cross-cylinder and astigmatic chart. We are inclined, in case of disagreement, to place the axis of the cylinder at the meridian indicated by the cross-cylinder. Nearly every eye with regular has also some irregular astigmatism, which is either not brought to light by observation of radiating lines or, if in evidence, it appears in a confusing way (as a group of clear lines, say at 10 o'clock and another group not at right angles to the first group). It is our belief that the cross-cylinder, used in the manner described by Jackson and Crisp to determine the axis of the cylinder, insures the placing of the cylinder at an axis that will serve the patient best for visual acuity and comfort, although this axis may not coincide precisely with the axis as indicated by the line or lines selected as the most distinct on the astigmatic chart.

ATTITUDE OF EXAMINER

If an examiner is to have the greatest number of successes—and as a corollary, the fewest number of failures—he must study the personality of each patient. Therein lies the fascination of the art of refraction for any one who enjoys contacts with all sorts of human beings. As there is no man or woman so utterly depraved that there is not some bit of goodness lurking in the depths, so there is no one (unless he is an imbecile or still lower in the grade of intelligence) that cannot be aroused to some degree of intelligent cooperation in this test for glasses by the right "approach" on the part of the examiner. The examiner should have broad human sympathies and a clear understanding of the diverse attitudes of those who seek his services. He should be tolerant of all, even of those whose point of view differs markedly from his own. The effort to understand the other fellow will engender a sympathy between examiner and examinee that will tend to secure that very necessary cooperation without which the subjective test is likely to fall short of its most perfect results. Thus, too, is created in the patient a confidence in the examiner whose words of admonition and advice, when the new glasses are first worn, will not fall on deaf ears. To the patient with compound hyperopic astigmatism who has been carrying on with spheres or no glasses at all, the induction into his new compound lenses with, perhaps, the cylinder placed at an oblique axis, is a trying period and unless he be fortified with a full explanation of the discomforts and distortions which he is almost sure to experience he may discard his glasses forthwith, heaping maledictions on the head of the unfortunate examiner, whose reputation is bound to suffer by the oft repeated tale of how "I couldn't wear his glasses—they nearly drove me wild."

THE USE OF CYCLOPLEGICS

The controversy between the habitual users of cycloplegics, the occasional users and the nonusers, which has raged with much ardor for the last half century, still continues.

We are firm believers in the use of cycloplegics. Furthermore, we are convinced that their use should be extended far beyond the usually accepted limit of 40 or 45 years. On this point we are in agreement with Sumner.[9]

It is freely admitted that careful users of noncycloplegic methods often obtain results that are satisfactory to their patients. Any method that will enhance the precision of noncycloplegic refraction is worthy of commendation and it is for this reason that Dorland Smith's[10] method of cyclodamia has its distinct and useful place. Such a method, in our opinion, should be regarded as a useful adjuvant and should only rarely be relied on exclusively to determine the prescription.

Our belief based on long experience is this: A knowledge of the static refraction is necessary, not only for the present prescription, but also for the future management of the case. The behavior of the accommodation is often misbehavior; in other words, it is rarely possible to estimate in any given case whether we are dealing with a factor that is nearly constant or decidedly variable, and such uncertainty is abhorrent to one who desires to keep his feet on solid ground.

We habitually use a cycloplegic (homatropine) up to the age of 55 or even 60 and find two principal advantages in this practice: first, we put in temporary quiescence the accommodation which in so many of these uncorrected or partially corrected cases of presbyopia is in a state of pathologic tension due to the outrageous burden that has been imposed on the ciliary muscle; second, we often unearth small, but important, astigmatic errors which have eluded us in the preliminary test. It goes without saying that the mydriasis is not attempted if we have the faintest suspicion of glaucoma, and is always promptly counteracted at the conclusion of the test with physostigmine (eserine) or pilocarpine.

One who has been imbued with the many indubitable advantages of the shadow test and who, through constant practice, has become adept and accurate in his estimates, may reach such a degree of certainty that he feels that subjective tests are of minor importance; that if there is a discrepancy between the shadow estimate and the patient's choice of lens, there must be something wrong with the patient. Such a "mechanistic" view is no more tenable in the field of refraction than it is in the vast problems of the universe. The examiner should remember that it is his function to give comfort to a patient as well as to a pair of eyes, rather than to justify his superlative ability as a skiascopist. The subjective test remains today, as always, the court of last appeal.

It is our opinion that all children up to the age of 15 (and many older) should have the benefit of a test under atropine. The strength of the solution will vary with the age of the child. We prefer 0.5 per cent up to 10 years and 1 per cent over 10 years, used three times a day for at least three (preferably four) days prior to the test. Rather than forego the advantages of atropine, we prefer to adopt the plan of E. V. L. Brown[11] and use drops in one eye at a time, thus permitting the child to continue school work without interruption. We have never seen any disadvantages from this practice. For young persons with myopia we insist on a longer period of atropinization (one week or more) before making the test.

THE FINISHED PRODUCT

The mechanical art of the optician reaches its highest expression in the United States. More beautiful designs are constantly being developed. Prescription opticians are skilful in adapting the frame to the face so that the combination is harmonious. It is surprising, therefore, to note how frequently the "fitting" falls far short of an ideal. Rarely, indeed, do our patients who have been previously examined appear with frames which are not too wide or too narrow, the latter defect being almost universal in "pince-nez." The lenses are frequently too far from the eyes; they are placed too high or too low; possibly the upper edge of the lens comes in contact with the eyebrow or the lower edge with the cheek or nose. Only rarely is there the slight forward tilt of the lens, the so-called pantoscopic position, which is necessary in reading glasses to insure that there is a minimum of obliquity in looking through the lens. Bifocal segments are too often improperly centered; they are often too large to permit easy side

[11] Brown, E. V. L.: Personal communication.

glances through the distance portion. The adoption of small (13 or 14 mm.) round or D-shaped segments, with the lower edge terminating several millimeters above the lower edge of the frame, is a great boon to many who, literally, have found the old style large segments occupying from one quarter to one third of the total lens area, a serious "stumbling block."

In this paper we have purposely omitted consideration of the ocular muscles, as we desired to limit our discussion solely to problems of refraction. We do not neglect a careful estimate of the heterophorias, the nearpoint of convergence, convergence or divergence excess or insufficiency, and our refraction estimates are often modified by these findings. We have been especially impressed with the frequency of hyperphoria and thoroughly believe in its correction.

But, as Kipling would say, "that is another story," which we may tell at some future meeting of the section.

ABSTRACT OF DISCUSSION

Dr. William H. Crisp, Denver: No man who is not in love with his job can do good refraction, and if any young man is considering the study of ophthalmology and likes it all except refraction, he had better get another job, because he will not be fair to the great majority of his patients and he will not be fair to the profession of ophthalmology if he cannot do good refraction. I had an excellent example recently of the influence small differences in adjustment of the frame have on the patient's comfort. A man with high myopia and some astigmatism, who does a good deal of close work, had come to me for refraction and returned complaining rather vaguely of discomfort in using his glasses. He was disturbed by the reflection that occurs from the back to the front of the lens and then into the eye. I tilted his glasses down about 5 degrees more, and he called me in a day or two to say he was very comfortable. In the work of the American Board for Ophthalmic Examinations, in the refraction section, we have been distressed by one thing. I believe that every refractionist should be familiar with some precise test for measuring astigmatism other than retinoscopy. I was asked yesterday if we did not pass a man because he did not use a cross cylinder. I denied the imputation, but I believe every candidate should be able to use either the astigmatic dial or the cross cylinder. If we do not take care of our refraction work we shall certainly encourage the development of optometry as a profession.

Dr. C. W. Rutherford, Iowa City: I am going to mention some observations that have come to me in the training of young men to do this work. We have had until recently a two-year service. We are now trying the three-year plan. The first duty of an intern is to pay his way by becoming proficient in refraction, and the more proficient he is the more rapid will be his advancement. We concentrate on that feature. The intern is fortunate in that he has available consultation at all times. We do not accept any student for a short period. The report sheet contains everything that we believe is essential to writing a prescription, and some things that may not be essential but which we wish to know. These reports all come over my desk and they are checked item by item. After the intern has had about five or six months' experience we notice there is a tendency to leave out this little point or that, and unless corrected, the next week he is leaving out more little points. The remedy is to have him send for his patient to come back. It is an inconvenience that he does not want. He learns to do his work properly the first time. The reason the intern omits these points is that he gets overconfident and thinks he can understand his patient without going through all the tests. I want to emphasize that poor training is responsible for more inexpert refraction than any other one thing. If we kept these students down to facts, if we kept them from acquiring unwise procedures and slipshod methods, kept them right on the line, by the time their two or three years has expired they have acquired habits that are rather firmly established.

Dr. Laura A. Lane, Minneapolis: I believe that even in our higher institutions we do not devote enough time to teaching refraction. I had a great deal of difficulty when I first began because I worked with a preceptor, a man finely trained in his work, but who did not devote much time to teaching refraction. Refraction was the hardest subject for me before the ophthalmic board. I had to spend much extra time on this subject but it has paid in many ways. If we do good refraction work, it not only benefits the patient but extends further than we know. It makes the patient easier to live with and it brings us other patients. The authors spoke of glaucoma. I agree that the patient should be given every possible aid in the way of obtaining sight, and I am often surprised to have patients say they have been told that glasses cannot do them any good. I recently had an experience with a man who was a high-class mechanic, who had glaucoma. He was put into a home and told that there was no use to go to a physician. He had less than 3/60 vision in one eye. In six months he came up to 6/20 + without operation. He goes around alone and is a much happier person. Dr. Green suggests the use of homatropine up to the age of 55 or 60. I have not used it beyond 48, and I am glad to know that it can be used safely up to 60.

Dr. E. L. Jones, Cumberland, Md.: I am happy to see this paper on the program. It will have a tendency to revive greater interest in one of the most important fields in ophthalmology. Twenty years ago I began to realize some things that are not commonly accepted, and one is the importance of absolutely exact astigmatic correction, the use of all the time and patience necessary, and most of all one's best efforts in refracting people who have reached or are long since past the presbyopic age. I am also pleased to see that the authors are coming out positively on the necessity of having the pupils somewhat dilated in these cases. It is impossible to get true fixation of the axis in the small pupils of old persons. I do not dilate the pupils with full strength homatropine as in young persons. I never do it without taking the tension, and omit the weak mydriatic if the tension is elevated. Eye-stress acts on the autonomic nervous system, causing cold hands and feet and many other things from disordered vital organs; and improvement in these persons oftentimes depends just as much on the exact correction of a little astigmatism, whether it is by itself or in the presence of several diopters of hyperopia or myopia, as on correction of larger defects. Many persons can be enabled to go on to useful lives by attention to these details just as much as by a major surgical operation for the removal of gallbladder or appendix when these cause ill health or invalidism.

Drs. Hans Schroeder, New Orleans: Refraction is highly interesting. It requires a thorough knowledge not only of anatomy, physiology and pathology, but also of physics, mathematics and psychology. More than a third of the cranial nerves go to the eye. This seems significant and leaves room for research on the relation of eye abnormalities to systemic diseases and vice versa, especially the significance of refraction in this respect.

Dr. S. B. Muncaster, Washington, D. C.: I find the ophthalmometer a help in nine out of ten patients in making an examination for astigmatism of the cornea. It takes time to learn how to use this instrument. Dr. Bull taught me how to use the ophthalmometer in 1890 when he and Javal were perfecting the instrument. I believe I brought over the first ophthalmometer to this country.

Dr. Thomas D. Allen, Chicago: I want to protest against the high-handed methods frequently used by physicians, particularly those who dilate pupils and order glasses directly from the observations with the retinoscope without much trial case work, in saying to the patient, "These are the right glasses and you must wear them even if they are uncomfortable." The patient is the final judge. He comes to us for relief. After we have done our work carefully we should see that the patient gets into the hands of some one who can fill the prescription accurately. I should like to ask a question: Why is it we occasionally see a patient who should wear a cylinder say of 3 diopters, but who prefers a sphere even although after careful checking, with drops and without, no sphere is found?

Dr. John Green, St. Louis: I agree with Dr. Crisp that the tendency to determine the strength and axis of the cylinder solely by means of the retinoscope is to be deplored. Dr. Rutherford has outlined a correct method of teaching refraction. The student is not primarily thrown on his own resources, he is not allowed to work out his own salvation but is made to consult with instructors in charge of the work. If he becomes careless he is quickly brought on the carpet and made to see that he cannot neglect a single detail of the test and be a successful worker. Dr. Lane has pointed out the change in disposition of some patients who have received the proper correction. I am sure that is perfectly true. We know that children, after receiving appropriate lenses, especially if they have compound hyperopic astigmatism, are tremendously altered, mainly because they are able to cope with their school tests. A child develops an inferiority complex if he cannot do as well as his fellows in school; but when we give him better functioning eyes he quickly gains confidence. Dr. Muncaster's praise of the ophthalmometer I agree with, with reservations. It is a useful instrument and a time saver in many instances; but the information thus gained should be regarded as merely suggestive. The astigmatism of any eye is a composite of several factors and it is not wise to pin too much faith on the corneal element alone.

SOME UNTOWARD EFFECTS OF ACETYLSALICYLIC ACID

R. W. LAMSON, Ph.D., M.D.
AND
ROY THOMAS, M.D.
LOS ANGELES

It has been emphasized many times that allergic responses may be precipitated or aggravated by a wide variety of agents. Ample evidence has been published to prove the importance of drugs in this connection. The one that receives most frequent mention—probably because of its widespread use—is acetylsalicylic acid. Not a few patients are aware of their clinical sensitivity to this drug before they consult an allergist; this was true in three of the four cases mentioned here and usually it is advisable to accept the patient's statement without further experimentation. A few brief reports of cases may emphasize this and other points.

REPORT OF CASES

Case 1.—Mrs. C., white, aged 54, complained of a cough, paroxysms of dyspnea with wheezing, and frequent attacks of bronchitis.

For fourteen or more years she had had attacks of bronchitis, and several years before her present illness her condition was diagnosed pulmonary tuberculosis of the fibroid type. The remainder of the history was not relevant to the present complaints.

Her family history was indefinite as to allergic tendencies.

In July, 1928, without associated symptoms, she experienced her first attack of paroxysmal dyspnea. This was of short duration and was not repeated for a month or two. In the spring of 1929 these attacks became more severe, and ultimately the symptoms were practically constant. The dyspnea was aggravated by exercise or by coughing. The patient stated that she was sensitive to acetylsalicylic acid, and this was borne out by her severe and protracted response to a small dose administered without her knowledge. Epinephrine usually afforded relief but was of little value in this attack.

Allergic tests failed to demonstrate any etiologic factor. A few months later the patient was urged by a friend to try a new "cure" for asthma. To have a margin of safety, she took only half of the dose usually recommended. The attack did not seem to be severe, and she tried this new remedy as a *substitute* for epinephrine. In a few minutes after the powder had been ingested the symptoms became acute and one of us (R. T.) was called, too late to see her alive, as she died in less than half an hour after her attempt at self medication.

Case 2.—Miss C., aged 62, complained of a cough, severe dyspnea and some wheezing. Her present illness began about sixteen years ago in February, while living in Michigan. At first the symptoms suggested bronchitis. This was accompanied by some wheezing, which readily responded to simple remedies. Her history suggests a pollen etiology, but she has not had the allergic tests. She followed the advice of a friend and tried one 5 grain (0.3 Gm.) tablet of acetylsalicylic acid in an attempt to relieve a mild attack of dyspnea. Her description of the severe aggravation of the symptoms that followed is more than presumptive evidence that the drug was not well tolerated. The list of cultists she has consulted and the nostrums she has tried would occupy several columns. She was asked whether she had ever experienced an unpleasant reaction from any "patent medicine." In reply to this she vividly described her response to the "cure" mentioned in the previous history. She also took but a part of one powder, and the attack of dyspnea that followed was so severe that she became unconscious; she stated that the physician remained in attendance for several hours. She had no idea of the contents of this "cure," so a psychic response seems improbable.

Case 3.—Mrs. M., aged 55, complains of recurrent attacks of itching of the nose and sudden nasal obstruction; frequent attacks of dyspnea with wheezing, and a cough which often results in her raising "tapioca" sputum.

In the past eighteen years her condition has become progressively worse, until she now has paroxysms of dyspnea practically every two hours. She is always worse in hot weather, is improved at the beach and usually obtains complete relief when on a fishing barge about two miles off shore. Other facts in her history point to some sensitivity, but thus far allergic tests have not been made.

A friend advised her to try the same "cure" used by the patients in the previous reports. The ingestion of one of these powders was followed by an attack of severe dyspnea which required epinephrine for relief. Her history is not definite with respect to drug idiosyncrasies.

Case 4.—Mrs. H. M., aged 51, had symptoms suggesting a true hay fever in the spring and summer of 1913; she also experienced mild wheezing but no acute paroxysms. Occasionally she used acetylsalicylic acid for its analgesic effect. This drug always caused marked exacerbation of nasal symptoms. There are no indications of an abnormality of any of the more important systems.

The family history reveals that her mother may have had bronchial asthma.

Since 1925, the dyspnea and wheezing have become more severe, and she was not expected to recover from one or two attacks. Allergic tests have failed to reveal any etiologic agent. She, also, was advised to try the "cure" under discussion. One powder, employed to relieve a mild paroxysm, markedly aggravated her symptoms. Five hours of self medication afforded no relief. A physician finally interrupted the attack after hypodermic medication. She was not then aware of the composition of the powder.

The nostrum referred to in these case histories is "M. Matte's German Asthma Powder," which is extensively used by asthmatic patients in this territory. A communication addressed to the Bureau of Investigation of the American Medical Association brought the reply that preliminary and qualitative tests showed the presence of acetylsalicylic acid and caffeine. Bromides, iodides and local anesthetics were not found. There is nothing on the label of these powders to indicate their composition, but it would appear that the two ingredients caffeine and acetylsalicylic acid are the most significant and possibly the only active ones in the nostrum.

SUMMARY

1. Drug idiosyncrasies in allergic patients are not infrequent. An abnormal response to acetylsalicylic acid is probably more common than to any other drug.

2. Nostrums containing this compound are not "harmless" from the standpoint of the allergic individual. Four cases are reported in an effort to substantiate that point of view. One patient died within a short time after taking a small dose of this nostrum.

1930 Wilshire Boulevard—1136 West Sixth Street.

A CONDITION SIMULATING HUMAN SCLERODERMA IN RATS INJECTED WITH PARATHYROID HORMONE

HANS SELYE, M.D.
BALTIMORE

In the course of the collection of experimental data on rats injected with parathyroid hormone[1] it became evident that young suckling rats receiving in some cases only a single injection of 5 units of parathyroid extract intraperitoneally develop within some days a specific skin disease.

This condition presents itself first as a hardening of the skin on the back, extending bilaterally from the head to the lower border of the ribs. Within two or three days the hair over these areas begins to fall out and concomitant with these phenomena the skin becomes harder and thicker. Ulceration of these symmetrically arranged affected areas takes place in some parts, and finally after healing a bare, hairless, atrophic skin results.

When examined histologically, the areas under consideration show a marked hypertrophy of the fibrous tissue in the skin, between the epithelium and the layer of the hair follicles. The areas of fibrosis tend to degenerate, and in sections stained by von Kossa's method amorphous deposition of calcium may be seen in the degenerated and necrotic parts. The calcium deposition appears to be secondary to the initial fibrosis of the skin because large areas showing marked fibrosis are free from calcium deposition.

This condition in rats possesses striking points of similarity with the human diseases known as scleroderma and sclerodactylia, in which conditions there occurs a connective tissue hypertrophy in the skin, likewise mostly in symmetrical distribution, together with degeneration of this hypertrophied connective tissue and ulceration of the affected areas. Finally healing results in the atrophic skin over these areas.

A perusal of literature on this disease in man tends to indicate that scleroderma may be related to hyperparathyroidism.

The available reports in the literature tend to suggest that the parathyroids play a rôle in scleroderma, because in most cases the blood calcium is high. Calcification of the skin and the subcutaneous connective tissue has been reported in many cases,[2] and Weidman[3] has even reported calcification in the arteries in a newborn baby affected with scleroderma.

The present report offers further substantiation for the concept that hyperparathyroidism is related to scleroderma. It would seem that a number of human diseases of hitherto obscure origin are related to parathyroid malfunction. Osteitis fibrosa represents one manifestation of this condition, as Jaffe, Bodansky and Blair demonstrated. As this paper indicates, scleroderma seems to be another such manifestation.

It is perhaps of some interest in this connection to mention another condition which, in the light of experiments now under way, appears also to be related to parathyroid malfunction. This condition is known as marble bone disease (morbus Albers-Schönberg). In fact, the experimental observations indicate that a marked sclerosis with eburnation of the metaphyseal regions of the bones can be produced when parathyroid hormone is administered to young rats in increasingly graded doses. The condition resembles strikingly the marble bone disease seen in man. It is interesting to note that Péhu, Policard and Dufourt[4] described recently a case of marble bone disease with high blood calcium and marked hypertrophy of the parathyroids.

It would be interesting in the light of these observations to determine the effect of parathyroidectomy in the diseases mentioned.

THE CONTRARY THERAPEUTIC AND SEX RELATIONSHIP OF SYPHILIS AND TUBERCULOSIS

WILLIAM F. PETERSEN, M.D.
AND
RUDOLPH HECHT, B.S.
CHICAGO

It might seem strange that an apparently significant though commonplace therapeutic phenomenon associated with the two most prevalent chronic diseases—syphilis and tuberculosis—should not be clearly recognized in clinical practice. That it is not so recognized can be due either to its very obviousness or to the fact that one so frequently thinks of the therapy in these two diseases from the purely specific, the etiotropic, point of view that the underlying autogenic mechanisms involved in clinical improvement are forgotten.

Successful therapy of syphilis, apart from the consideration of the primary lesion, involves the exposure of the spirochete. The physician seeks to "dig it out" as it were, and he does that by the catabolic activity of the alteratives—iodides, arsenicals, mercury, shock reactions. Activation phenomena, inflammation and digestion are encouraged. Protective tissue barriers are broken down by removing connective tissue and by increasing permeability of membranes. When exposed, the spirochete is apparently destroyed either by serum action (lysin, lipolysis, proteolysis) or by direct cellular effects.

The successful therapy of tuberculosis—and for the moment we would limit the discussion to pulmonary tuberculosis—is diametrically the reverse of this. Therapeutic measures that expose the tubercle bacillus, i. e., the catabolic phase of alterative therapy in the sense that we have just used it, bring about prompt activation, cavitation, dissemination, and death of the patient. Recognized therapy seeks rather to enhance the isolation of the virus, to accelerate the formation of connective tissue defense. When alteratives are used, the dosages are such as are presumably followed by anabolic effects.

We believe that the clinical appreciation of these therapeutic differences is too well established to require elaboration.

But if this antipodal therapeutic behavior is a fact, one might anticipate similar divergences of clinical reactivity to natural biologic alterations occurring in the

---

body, which may perhaps be interpreted from the same point of view.

Differences in the clinical behavior observed in syphilis and tuberculosis incidental to the sex of the patient form the basis for the present discussion.

Syphilis in women, as compared to that in men, is relatively benign. Quite apart from the fact that the primary lesion so often escapes detection, syphilologists have frequently commented on the fact that the secondary clinical manifestations are comparatively mild. And, of course, syphilis of the central nervous system occurs approximately in a ratio of 1 to 3 as compared to the male.

On the other hand, the female is much more susceptible to pulmonary tuberculosis. The death rate rises to a distinct peak by the time the patient is 15 years of age and remains much higher throughout the young adult period (chart 1).[1] The clinical recognition of this sex difference finds its expression in the old aphorism that "the tuberculous woman is killed by her menstruation" and in this marked susceptibility (which, incidentally, becomes apparent after the tenth year), and in the resulting death of the young female one can readily recognize the basis for the gradual increase in the resistance of a tuberculosis saturated population by the effectual method of selective removal of the susceptible female strain before reproduction.

Clearly, then, one finds a recognized therapeutic antagonism cropping out in the sex difference, the female being relatively resistant to syphilis and relatively susceptible to tuberculosis.

Fundamental differences inherent in the menstrual cycle of the female must be considered in the study of this interesting phenomenon, and in chart 2 we illustrate only some of the biologic alterations that we believe are of importance for the problem.

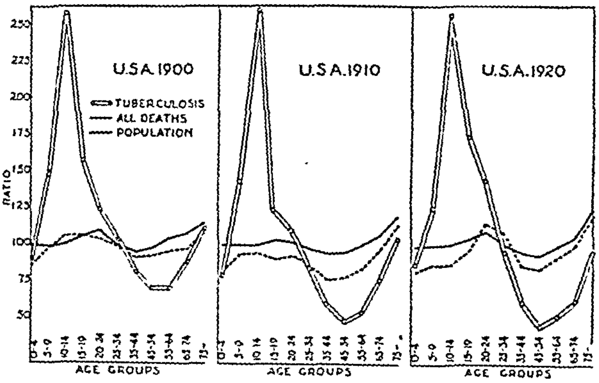

Chart 1.—This chart, prepared by Lloyd Arnold, illustrates the relative female mortality for tuberculosis as compared to the male mortality for different age groups (double line). The broken line represents the relative proportion of females in all deaths for each age group as compared to the males. The solid line represents the proportion of living females to males in the population in the various age groups. The proportion of females to males is indicated throughout on the basis that males are 100 per cent.

Arbitrarily dividing the cycle into two parts, (1) from the midmenstruum to the menstrual period (premenstrual period) and (2) from the menstrual period to the midmenstruum (postmenstrual period), we find premenstrually:

(*a*) A marked increase in capillary permeability.

(*b*) A relative increase in acidity.

(*c*) A reduction in the intermediary oxidation.

(*d*) An increase in the blood and tissue chloride with fluid retention.

(*e*) A decrease in cholesterol.

(*f*) A decrease in the carbon dioxide content.

(*g*) An increase in the activity of proteolytic and lipolytic enzymes.

(*h*) An increase in hormone activity (thyroid, suprarenals, pituitary, sex).

(*i*) Autonomic instability.

In the postmenstrual period these alterations are diametrically reversed. Of course, the magnitude of the changes varies in different individuals, but the general character of the rhythm is quite uniform (chart 2).

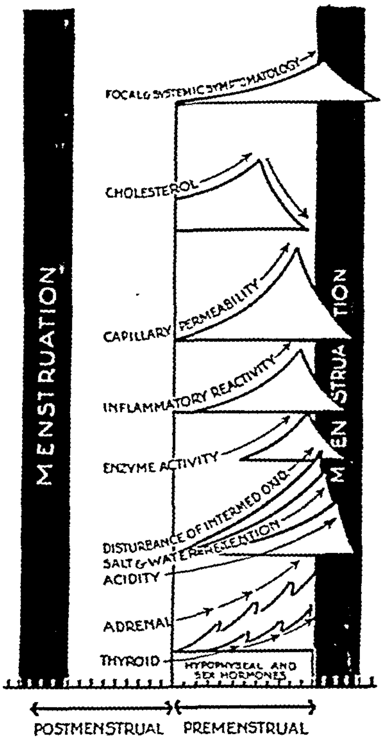

Chart 2.—Diagrammatic scheme to indicate some of the constitutional, hormone and chemical changes and their relation to the menstrual period. In the case of the hormones, there are apparently definite fluctuations in the secretion from the thyroid and suprarenal glands. This becomes evident from the autonomic instability that is apparent during the premenstrual phase.

We have mentioned but a few of the changes that are observed. Many more are perhaps of importance, including the calcium and potassium ratios, the blood sugar, and the amount and proportion of blood proteins.

The tuberculosis of the female is clinically more active premenstrually (temperature, tendency to hemorrhage, physical manifestations, symptomatology); postmenstrually it improves.

We can readily account for the increased activity. Increasing acidity of the tissues (evident in changes in the *p*$_H$, carbon dioxide content and intermediary oxidation), increasing capillary permeability, salt and water retention, and the activation of proteolytic enzymes increase the focal reactivity; decrease in cholesterol apparently lessens detoxication; the autonomic instability associated with the hormone changes accounts for the marked vasomotor fluctuations with the resulting alternation of vascular spasm and hyperemia. In this the relatively passive pulmonary circuit merely reflects changes taking place in the splanchnoperipheral balance of the distribution of blood.

The inflammatory reactivity, as measured in irritability of cells and permeability of capillaries, is distinctly enhanced. For the labile tuberculous process this means increased digestion, absorption of toxic materials, distribution of the virus (a premenstrual bacillemia has been demonstrated) a distinctly unfavorable constellation from the point of view of the clinical improvement of the patient.

Practically these changes correspond to those that are induced when a "shock" reaction, no matter how mild in degree, takes place in the patient, as, for instance, with the various forms of nonspecific therapy.

But the same biologic reorientation takes place every month with the syphilitic female. She, too, begins to "activate" her lesions, has a greater inflammatory reaction at the site of the accumulation of virus, and exposes and disseminates the virus.

---

[1] Chart 1 illustrates this point very clearly with American statistics.

Granted this profound and definitely periodic biologic upset and its inevitable effect on the existing tubercle and on the syphilitic lesion, the question immediately comes up, Why should the tuberculous woman die and the syphilitic woman improve? The answer must lie in the character of the virus. The activation of the tuberculous lesion involves not only profound intoxication but the dissemination of the virus. And this dissemination takes place at a time when the endothelium of the body is apparently in a receptive condition for implantation and proliferation of the bacilli. It must also be kept in mind that the virus of tuberculosis in its varied forms is relatively resistant to destructive influences. Contrasted to the tuberculous virus, the spirochete succumbs readily to humoral or cellular influences under conditions associated with the activation of inflammation. Therapy, as we have pointed out previously, is directed to that end.

Biologic changes incidental to the sex cycle in the female readily account for the peculiar lack of resistance of the female to tuberculosis and the relative benignancy of syphilis.

In many respects the change in the menstrual cycle can be compared with the effects that one sees with nonspecific or "shock" therapy. In both instances a disturbance is found in acid base equilibrium, in permeability, in endocrines and in the autonomic apparatus. In both instances identical effects on the localized foci of these two chronic diseases are found. Repeated "shock reactions" produced by peptone injection in tuberculosis induce activation, virus dissemination and death, as Holler determined. This is true, too, with large doses of biologic or chemical specifics such as tuberculin or "Sanocrysin." But repeated "shock" effects in syphilis are often followed by amazingly rapid therapeutic success in resistant syphilitic lesions and by some syphilologists are included as a routine in treatment, milk injections being given alternatingly with arsenicals or mercury. Engman and his associates are engaged in a study of the subject in this country.

It is probable that autonomic—and with it endocrine and chemical instability—may also influence the course of a syphilitic infection in the male, and Hecht[2] has sought confirmation by an analysis of the percentage of positive Wassermann reactions in individuals with genuine asthma, assuming that with each attack some degree of biologic shock effect will be associated, which ultimately must have an effect on a preexisting syphilis.

On this assumption the incidence of positive serum reactions (Wassermann or Kahn) should be less among asthmatic patients than the normal expectancy for comparative groups of the population.

In analyzing the results for Cook County Hospital, Hecht[2] found between 17 and 18 per cent of positive reactions for the years 1927 to 1932 for all services, including male and female. The true asthmatic patients, however, showed only positive reactions from 3 to 5 per cent. While, of course, not conclusive, the evidence seems to point in the direction that has been suggested.

SUMMARY

The established therapeusis of tuberculosis and of syphilis is antithetical. The alteratives,[3] in which category nonspecific therapy may be included, used in dosages followed by catabolic effects, are effective in syphilis but harmful in tuberculosis.

The biologic changes incidental to the female sex cycle have a corresponding contrary effect on these infections. Tuberculosis in the female is more malignant, syphilis generally more benignant, the reasons being found in the enhanced inflammatory reaction of the premenstruum.

The sex liability of the tuberculous patient finds clear expression in the mortality curve, while the relative protection of the syphilitic female is demonstrated in the greatly lessened incidence of neurosyphilis. Fundamentally, of course, the difference in the ultimate clinical effect of the identical biologic cycle lies in the ability or disability of the tissues and fluids of the body to dispose of the virus which is disseminated when premenstrual activation of localized lesions takes place.

---

[2] Hecht, Rudolph: The Wassermann Reaction in Asthma, Illinois M. J. **59**: *366* (May) 1931.

[3] We realize that the term alteratives is no longer in vogue among pharmacologists, but from the therapeutic point of view the classification is distinctly justifiable. Depending on the dosage, either anabolic or predominantly catabolic effects may be elicited.

HYPOPHYSEAL CACHEXIA (SIMMONDS' DISEASE)

WITH REPORT OF THREE CASES

HERMAN H. RIECKER, M.D.
AND
ARTHUR C. CURTIS, M.D.
ANN ARBOR, MICH.

In 1914, Simmonds[1] reconstructed from necropsy studies of two cases the clinical syndrome which results from destruction of the anterior lobe of the hypophysis. Since that time a number of cases have been described in the German literature, although none appeared in the English language until Graham and Farquharson[2] reported four cases in 1931.

Clinically the syndrome is characterized by premature senescence, generalized atrophy of all tissues, gradual failure of the body functions, mental torpor, apathy and death. The literature on the disease was reviewed to 1922 by Knoll,[3] and to 1930 by Werner Merz.[4]

ETIOLOGY

The destruction of the anterior lobe of the hypophysis may be caused by a number of primary and secondary conditions, and a review of twenty-four selected cases with autopsy observations from the literature suggests the following principal factors in the order of their importance: puerperal sepsis (septic embolus), 9; syphilis, 5; cyst, 4; tuberculosis, 2; unknown, 4.

The outstanding cause is that resulting from the infected embolus of puerperal sepsis, although ten of the twenty-four cases selected were in males. Three of the four cases reported by Graham and Farquharson[2] were from this cause. In Simmonds' original cases the arteriola propria hypophyseus (Benda) was involved; in a separate discussion of this phenomenon he says[5] that emboli are not rare in the gland, and while they cause small nests of infection in the neurohypophysis, in the anterior lobe such emboli may remain without reaction but give rise to anemic infarcts because the vessels of this part may be looked on as end arteries. In neither of Merz's[4] two cases was the entire lobe destroyed, but the eosinophilic cells were shrunken, while Budde[6] says that metastatic tumors invading this lobe increase the cachexia beyond that ordinarily produced by cancer. Many authors conclude that in certain cases there is no outstanding contributing cause of the disease except "endogenous constitutional factors."

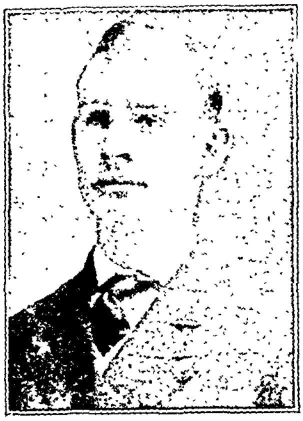

Fig. 1.—Patient 1, at age of 21, weighing 170 pounds (77 Kg.).

SYMPTOMATOLOGY

The basis of symptoms of Simmonds' disease is progressive atrophy of tissue. Weakness, loss of weight, rapid aging, falling hair, anorexia and loss of sexual function are prominent symptoms. An initial polyuria and polydipsia are frequently early symptoms and are emphasized in four of the twenty-four cases reviewed. The loss of sexual function is always present and is usually an early symptom. These two conditions are prominent in other diseases of the hypophysis and they serve only to direct attention to this gland.

Physical examination shows a shiny dry atrophy of the skin, sometimes confused with that of the thin subject of myxedema, a loss of body hair, the marked loss of weight, but most strikingly the premature aging of the patient. In men the testes are atrophic, the beard is scanty, the voice is hollow, and muscular strength is greatly diminished. An underlying pathologic process (i. e., syphilis, tuberculosis) often masks the conditions found with the exception of the premature senility. In addition, there is a definitely lowered basal metabolism, marked secondary anemia, and often a disturbance of the sugar metabolism. The prognosis is by no means fatal, particularly in cases resulting from syphilis, since Simmonds followed a case for eighteen years, and Oppenheimer[7] has had one under observation for twenty years.

Case 1 is typical of Simmonds' disease presumably due to acquired tertiary syphilis:

Case 1.—*History.*—A man, aged 47, an American laborer of Irish extraction, entered the University Hospital outpatient department, April 2, 1930, complaining of weakness, stiffness of the joints and constipation.

The patient's father died of uremia at 75 years of age, and the mother of apoplexy at 78. Aside from the tendency to arterial disease, the family history was negative.

The patient contracted syphilis and buboes at the age of 22, and was treated by means of mercury rubs at Hot Springs, Ark. Heavy indulgence in alcohol at the age of 42 led to sanatorium care, at which time the patient's right arm became temporarily paralyzed.

The present illness began following treatment for acute alcoholism four years before admission, when the patient weighed 172 pounds (78 Kg.), and his appearance of youthfulness caused him to be taken for his daughter's brother. The symptoms began rather acutely with weakness, followed by polyuria. He was admitted to a hospital at this time for treatment of polyuria, it being necessary for him to drink "a quart of water every few minutes." This symptom subsided in four weeks, and a gradual loss of weight and appetite supervened, the patient losing in two years from about 170 to 102 pounds (46.3 Kg.). For a time following the onset he was so weak that he could not get out of bed without assistance. Stiffness of the joints was prominent. Sexual powers disappeared immediately after the onset of the illness, and his appearance changed to that of a man of 60 years. The previously abundant body hair was lost. When first seen, the patient stated that he shaved every two weeks, felt cold and was quite unable to keep warm.

Examination.—The physical examination showed the patient's emaciation and his slow mental reactions; he was much older in appearance than his age indicated. The skin showed marked atrophy (Dr. Wile). The hair of the scalp was grayish and thin and consisted only of a border fringe. The body hair was absent with the exception of a slight amount on the forearms. The nails were extremely thin and fragile. Arcus senilis was present and the mouth was edentulous. The thyroid gland was palpable and was normal in size. The thorax was asthenic. The lungs were clear. The heart was perpendicular and not enlarged. The blood pressure was 98 systolic and 70 diastolic. The heart rate at rest was 72 per minute. The abdomen was scaphoid, with no organs palpable. The testes were markedly atrophic. The deep reflexes were present. There were no signs of syphilis of the central nervous system and no general or regional glandular enlargements.

Laboratory examination revealed: urine, clear, highest specific gravity 1.030; peripheral blood: hemoglobin (Sahli) 75 per cent; red blood cells, 3,600,000; white blood cells, 4,600; polymorphonuclears, 59 per cent; lymphocytes, 35 per cent; mononuclears, 2 per cent; eosinophils, 5 per cent. There was moderate anisocytosis and moderate central achromia of the erythrocytes. The Kahn test was 1 +; repeated, negative. The basal metabolism was —36 per cent. The pulse rate was 58. The stool was negative for parasites or ova and for occult blood. Roentgen studies revealed that the gastro-intestinal tract showed an atonic, ptotic, stomach without evidence of gastro-intestinal pathologic changes (Dr. Hickey). Examination of the chest revealed asthenic cage, some thickening of the

6. Budde, Max: Zur Kenntnis der bosartigen Hypophysengeschwulste und hypophysaren Kachexia, Frankfurt. Ztschr. f. Path. 25:18, 1921.

7. Oppenheimer, B. S., in discussion on Graham and Farquharson (footnote 2).

right apical pleura. There was emaciation. The heart was of the "drop" type, normal in size (Dr. Pierce). The skull was normal except for calcification of the pineal body; the sella turcica was normal (Dr. Hodges). Gastric analysis showed no free hydrochloric acid in any specimen (after histamine, 0.1 mg.). Dextrose tolerance tests were not done, and an examination of the spinal fluid was omitted.

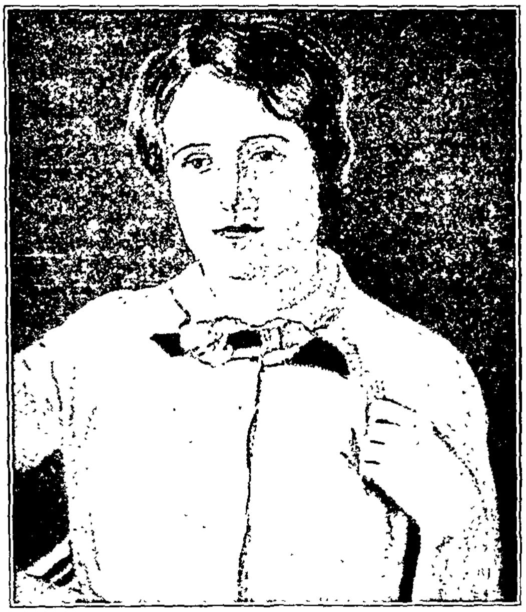

Fig. 3.—Patient 3, at age of 22, weighing 120 pounds (54.4 Kg.).

The case showed the following manifestations consistent with the syndrome of Simmonds' disease: premature senility, atrophy of skin and testes, marked loss of weight, low basal metabolism, loss of body hair, anemia, weakness, loss of appetite, chronicity, and subnormal blood pressure.

Course.—The case was diagnosed as myxedema and latent syphilis, and the patient was admitted to the ward for treatment with desiccated thyroid gland. The basal metabolism was increased to — 1 per cent with a pulse of 112, but without subjective improvement in symptoms. After the paper by Graham and Farquharson and the subsequent discussion was heard, the diagnosis of Simmonds' disease suggested itself immediately, and further studies were carried out with this diagnosis in mind. Treatment has been continued with bismuth and iodide, and desiccated thyroid gland, and the patient has improved in cycles sufficiently to be ambulatory. By dietary treatment his weight has increased to 114 pounds (51.7 Kg.), and constipation is avoided. There has been no change in appetite or in strength.

Case 2 illustrates many features of Simmonds' disease as well as some features of acromegaly:

Case 2.—*History.*—An American laborer, aged 55, entered the University Hospital, Dec. 17, 1925, complaining of weakness.

The father died of arthritis at 71 years of age and the mother died of apoplexy at 65. Aside from a tendency toward arthritic diseases, the family history is negative.

The patient stated that he did not have syphilis and gonorrhea by name and symptom. Little alcohol had ever been used.

At the age of 35 the patient began to notice weakness. Associated with this symptom he had frequent attacks of nausea and vomiting, which lasted eight years. Numerous sick headaches were present with pain over the right eye and in the crown of the head. His weight during this time decreased from 203 to 170 pounds (from 92 to 77 Kg.). At the age of 41 he first noticed diplopia, which had persisted periodically since. His headaches were relieved by glasses. During the past fourteen years he had noticed that he had slept more than normally. His bowels had been moderately constipated during the past twenty years. During the past twelve years he had noted a loss of 10 pounds (4.5 Kg.) and a marked disappearance of his facial hair, so that it was necessary to shave only once a week. During the past four years the pubic hair had become scanty, and the axillary hair disappeared three years before entrance to the hospital. Since the onset of his trouble he had been compelled to do lighter work and during the past six months his weakness had been so great that he spent most of his time in bed.

The patient was married at 20. His wife was living and well. This union produced five pregnancies; two children, living and well, and three miscarriages. During the past ten years the patient noticed that his sexual capacity had become limited.

Examination.—The patient was fairly well developed and had a blank facial expression. The skin appeared to be flabby but otherwise was normal. The hair of the scalp was fine in texture. The body hair was absent in the axillae and on the chest and was scanty over the pubes. The pupils were round and equal, but the left pupil was sluggish in its reaction. There was failure of convergence of the right eye and a definite blindness of the temporal half of the right eye. The teeth showed much caries. The voice was not hoarse. The thyroid gland was palpable. There was a dorsal kyphosis of the thoracic vertebra. The lungs were clear. The heart was slightly enlarged. The blood pressure was 130 systolic and 70 diastolic. The rate was 84 and the rhythm regular. The abdomen was normal in appearance. No glandular enlargements were palpable. No signs of syphilis of the central nervous system were present.

Laboratory examination revealed the urine normal at all times; hemoglobin, 65 per cent (Sahli); red blood cell count, 4,420,000; white blood cell count, 6,300; polymorphonuclears, 51 per cent; lymphocytes, 39 per cent; mononuclears, 6 per cent; eosinophils, 3 per cent, and basophils, 1 per cent. The red cells were normal except for moderate achromia. The Wassermann test was negative. The basal metabolism varied from — 18.6 per cent on the first determination to — 23 per cent (Tissot). The spinal fluid was normal. Detailed studies of the sella turcica showed practically complete absorption of the lime salts in the lower and posterior clinoids. The destruction was suggestive of neoplasm. Examination of the fundus by Dr. George Slocum showed angiosclerotic changes in both eyes with marked edema. The right eye showed optic atrophy and a loss of convergence. The visual fields showed a right temporal hemianopia. The dextrose tolerance test was: fasting, 0.083 per cent; first hour, 0.114 per cent; second hour, 0.087 per cent; third hour, 0.083 per cent. The urine was normal in all specimens during the course of the test. The diagnoses of pituitary tumor, right temporal hemianopia and peripheral arteriosclerosis were made. The patient died very suddenly, and necropsy showed the following:

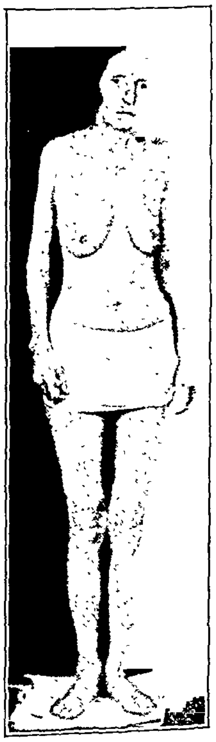

Fig. 4.—Patient 3, at age of 41, weighing 100 pounds (45.4 Kg.).

Necropsy.—The general nutrition was good over the abdomen and thorax but showed some wasting over the extremities. The facies was thin and somewhat acromegalic in type. There was atrophy of the muscles of mastication. The right eye showed a superior lateral strabismus. There was a moderate increase in the size of the thyroid gland. The thorax was essentially normal. The skin was inelastic and soft. The hair of the head was abundant and fine in texture. The beard was scant and fine. The axillary hair was absent. The pubic hair was scant, fine and delicate. There was a yellow purulent discharge from the right ear. The head was normal. The brain was not sectioned. The hypophysis was represented by a large tumor mass, completely filling the large sella. It was very soft in consistency and was pedunculated. The infundibulum was much thickened. On removal, the mass was necrotic and was partially destroyed. There was compression and thinning of the right optic nerve. It was no larger than a few strands of thread. The left optic nerve was also somewhat thinned. The petrous portion of the temporal bone was removed, disclosing a right purulent otitis media and mastoiditis. The gross examination of the thorax and abdomen and their contained organs was negative except for edema, congestion and a seropurulent exudate expressed from the right lung. The pelvis showed an apparently normal penis and scrotum. The testes showed moderate fibrosis.

There was a malignant adenoma of the pars intermedia (adenocarcinoma) of the pituitary gland. Abundant colloid was present. There was marked hypoplasia of the heart; atherosclerosis of the aorta; congestion, edema, and areas of healed chronic fibroid pneumonia of the lungs. The bronchial nodes, thyroid, spleen, small intestine, appendix, stomach, pancreas, liver, prostate, seminal vessels and bladder were essentially normal. The suprarenals showed extreme congestion and small inflammatory infiltration of the cortex. The testes showed complete aspermatogenesis. Patches of fibroid atrophy were present not resembling syphilitic areas. The stroma was relatively increased and edematous. The interstitial cells were markedly atrophic.

The clinical diagnosis was pituitary tumor, hypopituitarism, bronchopneumonia, acute right-sided otitis media and mastoiditis.

The pathologic diagnosis was malignant adenoma of the so-called pars intermedia (adenocarcinoma) of the pituitary gland; hypopituitarism; aspermatogenesis; atrophy of the bronchial nodes; old obliterative appendicitis; old fibroid pneumonia and localized pleural thickenings; nephrosis with glomerular hypertrophy; general passive congestion, and parenchymatous degeneration.

Although case 2 presents some features of hyperpituitarism and some of hypopituitarism, many features of Simmonds' disease are present. The process probably began as a nonmalignant adenoma of the hypophysis and as it increased in size it eventually destroyed the anterior lobe. The weakness extended over a long period and apparently was the first symptom; the loss of sexual powers and the loss of body hair were the last to appear. The appearance of premature aging was not striking, owing to the retention of body weight. Other features of senility praecox were present, however. This case illustrates Erdheim's[8] belief that adenomas causing acromegaly have the symptoms of both hypopituitarism and hyperpituitarism.

Case 3.—*History.*—A white woman, aged 41, a native of Michigan, complained of weakness and loss of weight. The father died of a stroke at the age of 70 and the mother died of pneumonia at 60.

After numerous heterosexual experiences the patient was married at 20, from which union there is one child living and well. The first pregnancy was followed by a series of miscarriages.

The menstrual periods ceased at the age of 26. At 30, she noticed a lack of sweating, and eczema of the skin during the winter months. At this time she worried about her appearance of "growing old" and of increasing weakness. At 36 she experienced a "stroke," which left a residual paralysis of the right side of the face and deviation of the right eye. Recently there had been nasal trouble, a feeling of constant chilliness, weakness, poor appetite, loss of libido, and loss of memory. There was a total loss of weight of about 20 pounds (9 Kg.) during her illness.

Examination.—The patient had the appearance of a woman of 60, emaciated, weighing 80 pounds (36.3 Kg.). The skin was atrophic, dry and cold. The eyebrows were sparse; there was no body hair; the hair on the scalp was dry, grayish black and fairly abundant. The eyes showed a divergent attenuating strabismus on the right; the pupils were fixed and there was keratitis. There was marked oral sepsis. There was syphilis of the buccal cavity and of the soft palate. There was a speech defect similar to that of dementia paralytica. The reflexes were normal. The blood pressure was 120 systolic and 70 diastolic.

Laboratory examination revealed: basal metabolism, —28; pulse, 68; Kahn test, 4 plus; spinal fluid, negative; hemoglobin, 90 per cent (Sahli); red blood cells, 4,740,000; urine, clear. Dextrose tolerance test: fasting, 95 mg. per hundred cubic centimeters; first hour, 102; second hour, 90; third hour, 83.

Manifestations indicative of Simmonds' disease were: premature senility, atrophy of skin, loss of body hair, loss of libido, mental deterioration, low basal metabolism, loss of weight, weakness, and the sugar tolerance curve.

COMMENT

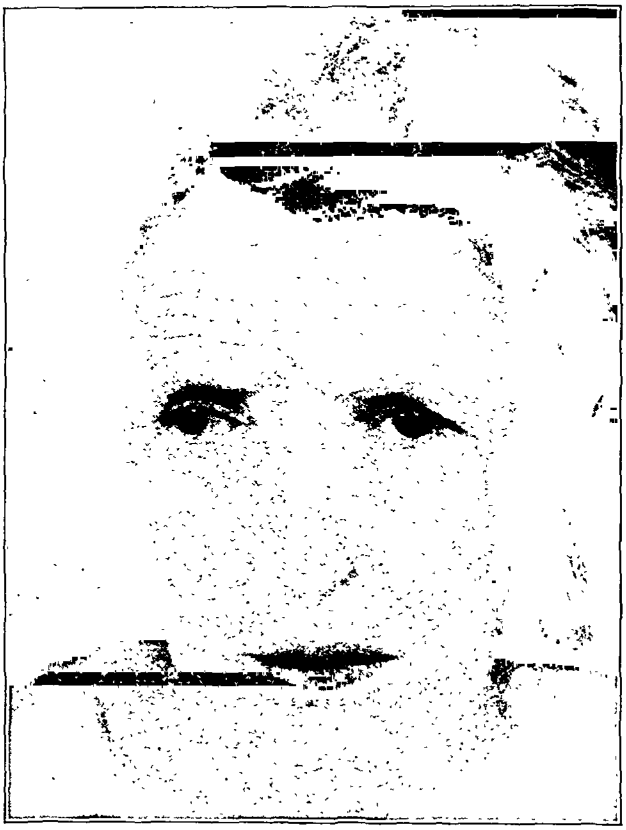

Fig. 5.—Patient 3, at age of 41.

The disease can be recognized clinically only by having in mind the possible etiologic factors and the chief presenting manifestations, which are premature aging together with generalized atrophy of the skin and other organs. Mental lethargy might be due in part to secondary nutritional disturbances and to a low metabolism. The latter, with changes in the sugar tolerance curve, is seen frequently in tumors of the pituitary gland not associated with the Simmonds syndrome. Erdheim[8] believes that the eosinophilic adenomas resulting in acromegaly are not examples of total hyperpituitarism, and that they may have certain common elements with Simmonds' disease, such as loss of strength, marasmus and a genital disturbance.

Merz[4] has reported Simmonds' disease and exophthalmic goiter in the same patient with autopsy observations. There is considerable discussion in the literature about the relation of hypophyseal cachexia to involvement of the other endocrine glands. Several cases have been mistaken for myxedema, and one experienced clinician on our staff remarked that case 3 was one of polyglandular dystrophy. The syndrome should be looked for in all tumors of the hypophysis, five cases due to cysts being reported in the continental literature. The clinical picture undoubtedly must be based on the absence of the specific growth secretion from the anterior lobe even though such a picture has not been presented in experimental animals. Generalized hypertrophy was demonstrated by Evans when he administered the secretion of the lobe to rats, and general atrophy is that seen in disease which destroys the glandular element in man. It seems established from a number of German autopsy reports that neither the posterior lobe nor the pars intermedia and related cells of the floor of the fourth ventricle are involved, only the eosinophilic cells being destroyed.

---

[8] Erdheim, J.: Zusammenfassung über die Hypophysengewachse und Krankheiten, Ergebn. d. Path. 21: 547.

SUMMARY

1. An ambulatory case of hypophyseal cachexia, Simmonds' disease, in a man, aged 47, was characterized by an initial diabetes insipidus, premature senility, low basal metabolism and generalized atrophy. The history and serologic observations suggested syphilis as the etiologic factor.
2. A second case showed many characteristics of Simmonds' disease due to a tumor of the pars intermedia (malignant adenoma of the pars intermedia).
3. In a third case characterized by premature senility, syphilis was the etiologic factor.

Clinical Notes, Suggestions and New Instruments

THE PROLONGED USE OF SALYRGAN AS A DIURETIC: REPORT OF TWO HUNDRED AND SEVENTY INJECTIONS IN FIVE YEARS IN ONE CASE

Joseph R. Wiseman, M.D., Syracuse, N. Y.
Professor of Clinical Medicine, Syracuse University College of Medicine

Mrs. S., aged 58, a widow, seen, May 19, 1925, was short and very broad and weighed 280 pounds (127 Kg.). Her mother died of heart trouble and was also short and very stout. One brother, who was a little over 5 feet (152 cm.) tall, had a tremendous breadth of shoulders and weighed 230 pounds (104 Kg.). He had severe chronic nephritis with hypertension and died three years later. The father, who did not have this type of body build, died of an unknown cause.

The patient had been short of breath for several years, seldom walked, and had not been down town in five years. Her feet had been swollen for a considerable time; cough and sputum were present. During the past ten days the dyspnea had increased; she felt the beating of her heart in her throat and had been in bed three days.

The skin was flushed, the lips were cyanotic, and dyspnea was marked. The blood pressure was 190 systolic and 135 diastolic. The heart was considerably enlarged to the left; the sounds were clear and regular, with a waxing and waning of rhythm, and the rate was 170. The pulse was irregular, owing to a pulse deficit. The abdomen was very obese and the liver apparently much enlarged. Edema of the legs was present to the knees.

I withdrew 200 cc. of blood by venesection, after which breathing became easier. Large doses of digitalis were given. In a few days the rapid but regular heart action (probably auricular flutter) slowed to 120 and showed a disorderly irregularity of the fibrillation type. In ten days the rate fell to 80, and she was constantly kept under digitalis thereafter. Theophylline and theobromine had no influence on the edema. She was able to be up most of the time and in fair comfort but showed no striking improvement. In February, 1926, I aspirated the right chest and withdrew 2 quarts of straw colored fluid. She was then given ammonium chloride, 10 Gm. every twenty-four hours, followed by an intramuscular injection of 1 cc. of novasurol. In the following twenty-four hours she voided 5 quarts of pale urine, most of which was passed within the first twelve hours. The second day the urine fell to 1 quart and became dark colored. Under this treatment in the spring of 1926 her weight fell from a maximum of 288 to 218 pounds (131 to 99 Kg.) with much improvement in her sense of well being. The injections of novasurol were given at intervals of from three to seven days and were speedily changed to the intravenous route, because of the pain and infiltrations produced by intramuscular injections. The following year, 1927, novasurol was changed to salyrgan, which was continued throughout the remainder of her life. The intravenous injection of 2 cc. of salyrgan produced an average diuresis of from 4 to 6 quarts. If the doses came too close together a smaller amount of urine was obtained, and experience showed that an interval of from five to seven days was necessary for a maximum effect. The largest twenty-four hour response obtained at any time was 9 quarts. These injections were continued fairly regularly over a period of five years. Early in 1929, the diuretic response seemed to be a little less satisfactory (under 3 quarts), and at the suggestion of Dr. S. A. Levine of Boston, who saw her with me, I increased the dosage to 4 cc. During the next twenty-four hours 7½ quarts of urine was passed. As time went on, intravenous injections became increasingly difficult. Sometimes the same vein could be used for repeated injections, but at other times after a single injection the vein would become converted into a firm, fibrous cord. Slight leakage of the drug would cause severe pain, and on a few occasions a superficial area of skin necrosis followed. Early in 1931 it became necessary to change to intramuscular gluteal injections of 3 or 4 cc. doses to which procaine hydrochloride was added. The diuretic response appeared to be equally good; very little pain was felt, and no unfavorable results followed. (However, in two other patients similar injections in the upper outer quadrant of the buttock produced an intractable sciatic neuritis and I should hesitate to use this particular location again.)

Many examinations of the urine were made during the six years of observation. The specific gravity varied within wide limits, and was usually above 1.020. Occasionally a small amount of albumin was present, and often hyaline or granular casts. No definite changes were noted in the urine as the years went on, and careful observations failed to show any effects whatever which could be attributed to the prolonged use of mercurial diuretics. This is all the more remarkable as novasurol (merbaphen), and salyrgan (mersalyl) are 10 per cent aqueous solutions of organic mercury compounds containing about 33 per cent of mercury. A maximum dose of 4 cc. would therefore contain 0.13 Gm. (2 grains) of metallic mercury in soluble form.

May 11, 1929, after three years of diuretic treatment, a phenolsulphonphthalein test was made. Forty per cent of the dye was returned in the first hour and 28 per cent in the second hour, a total of 68 per cent of the dye. May 29, at 11 a. m., the blood sugar was 133 mg. and the nonprotein nitrogen 40 mg. The Wassermann test of the blood was negative.

The morning of October 27, a 3.4 Gm. dose of novasurol instead of salyrgan was given intravenously. In the afternoon the patient felt ill and had two rather severe chills. She became restless and more cyanotic but passed 7½ quarts of urine in twenty-four hours. Diarrhea developed, and a small amount of blood was passed by rectum. The gums became swollen and red. The symptoms all cleared within a week. Novasurol is apparently more toxic than salyrgan, and although the patient had tolerated small doses well during the first year of treatment, this large dose produced symptoms of mercurial poisoning.

An interesting observation was the persistence of a satisfactory diuretic response during five years of treatment and up to within a few days of death. The total number of injections (mostly salyrgan) was 270. The only occasions on which diuresis did not follow were when the abdomen was greatly distended with ascitic fluid, which presumably caused pressure on important veins. As soon as the fluid was removed by paracentesis, the diuretic response was at once restored.

Read before the Syracuse Academy of Medicine, Oct. 19, 1931.

The weight fell to 177 pounds (80 Kg.) during 1929 from a previous maximum of 288 pounds. It then slowly increased to 300 pounds (136 Kg.) at the end. Restriction of diet appeared to have little effect in producing loss of weight. Thyroid gland in doses as large as 15 grains (0.9 Gm.) daily made no impression. A salt free diet seemed to be of some benefit, but the patient refused to follow it for long. Remarkable fluctuations in weight took place. She would gain 10 or 12 pounds in twenty-four hours and lose an equal amount in the same length of time after an injection of salyrgan. She persistently refused to go to a hospital, and all observations had to be made in her modest home. She weighed herself on bathroom scales and had the urine measured by an attendant.

The blood pressure slowly rose to a maximum of 225 systolic and 130 diastolic. Auricular fibrillation continued throughout and was verified by electrocardiograms, June 24, 1930, and Jan. 29, 1931. The liver could best be felt after paracentesis. It was greatly enlarged, reaching 6 inches below the costal margin in the nipple line. The surface was smooth and the edge sharp. The spleen could not be felt. Fluid was aspirated from the right side of the chest three times in 1926 and 1927 but did not have to be withdrawn thereafter. Guinea-pig inoculation with pleural fluid was negative for tuberculosis. Abdominal paracentesis was done twice in 1928 and eight times in the last fifteen months preceding death.

Because of the distress and dyspnea suffered by the patient, hypodermic injections of morphine were begun in 1928. She gradually developed a habit and required moderately large doses. This incident was regrettable, but it would have been cruel to withhold the drug.

During 1930 and the early part of 1931 her condition slowly deteriorated with a steady increase in the general anasarca and a rising weight curve. The abdomen became tremendously large; the legs were huge, and the skin broke down in several places with a leakage of fluid from the tissues. Cyanosis became intense; she drifted into a somnolent state and died, March 16, 1931. An autopsy could not be obtained.

COMMENT

An obese woman with decompensated hypertensive cardiovascular disease was given 270 injections of novasurol and salyrgan over a period of five years.

An excellent diuretic response was maintained throughout. The prolonged diuretic treatment appeared to be without harmful effects on the kidneys or other organs.

608 East Genesee Street.

SPASMOPHILIC TETANY IN THE NEW-BORN

Edward G. McGavran, M.D., Sidell, Ill.

Tetany, or the spasmophilic diathesis, occurs chiefly in infants with some nutritional disturbance. Etiologically, it is looked on by some as a phase of status thymicolymphaticus. There is a definite constitutional predisposition to it. Some believe that it is a purely chemical deficiency due to a lack of guanidine and methylguanidine; others believe it to be a parathyroid dysfunction with a resulting calcium deficiency. According to Abt, the condition is seldom seen before the fourth month of infancy or after the third year. It is associated with a drop of blood calcium from 10 or 11 mg. per hundred cubic centimeters (normal) to 6 or 7 mg., with definite clinical symptoms, and complete recovery when the calcium content of the blood is restored to normal. It has been noted that few breast fed infants develop tetany and that most cases of this condition occur in bottle fed infants. Benjamin Kramer, in his discussion of Bass's[1] recent paper, said: "Although the clinical manifestations in all forms of tetany are identical, the chemical changes in the blood may be quite different. Although the serum calcium concentration is usually normal, there is justification for the assumption that the Ca^{++} ion concentration is reduced." As Bass and Karelitz have pointed out, although lowered calcium is an almost constant sign of tetany, equally low percentages may also be found in nephritis with no evidence of tetany. An absence of tetany has been reported with calcium of 5 mg. As Hess[2] states, the lack of complete harmony between the clinical manifestations and the calcium in the blood indicates that some factor other than the calcium concentration must be at work.

The case of tetany presented here I believe is one of the earliest reported. The condition probably existed before birth and was present at the time of birth. The patient developed typical spasmophilic convulsions thirty-six hours after birth. Unfortunately, calcium determinations of the blood were not possible; but the minutely typical clinical picture of emaciation, positive Chvostek's sign, Trousseau's sign, carpopedal spasm, convulsions starting with the eyes and extending to the extremities with clonic and tonic spasm, followed by laryngospasm and asphyxia, the prompt response to calcium therapy, and the subsequent normal development of the child justify the diagnosis. Whether this is a case of "infantile tetany" that so frequently in the literature is said not to occur in the new-born, or whether it is a case similar to the cases reported by Bass and Karelitz[1] is a purely academic question and cannot be proved because of the absence of blood calcium determination. The opinion exists that "infantile tetany" as an entity is a dietary deficiency disease. I find nowhere in the literature a suggestion that this condition must occur after birth. It could conceivably develop in utero, as it appears to have developed in this case.

REPORT OF CASE

The mother and father of the infant were both in good health. The mother, a primipara of a high strung, nervous disposition, took excellent care of herself throughout pregnancy in regard to diet, hygiene, and frequent and regular medical consultations. Pregnancy was normal. Labor was easy, normal, and of fourteen hours' duration. A full term, emaciated baby, weighing 6 pounds and 4 ounces (2,835 Gm.) was delivered. The cord was wrapped around the baby three times; the placenta showed large areas of degeneration. The baby breathed readily. He did not move readily; the arms were held in a spasm against the chest in the so-called obstetric position, the knees were flexed, and the feet were in equinovarus.

The baby was put in an improvised incubator and feedings were attempted every hour. He refused food and water. The condition remained about the same for thirty-six hours, after which convulsions started. These became steadily more frequent and severe. The body first stiffened slightly; then the eyeballs rolled back and twitched. The face became drawn spasmodically and the clonic state extended to the extremities. Breathing became labored. There were a few convulsive inspiratory efforts and then complete laryngospasm, with cyanosis, and finally a blue pallor. Recovery was quick; consciousness returned with normal respiration, but the infant seemed exhausted.

Trousseau's sign was present from the time of birth without pressure being applied. Chvostek's sign was easily elicited between convulsions. Also, Weiss's orbital spasm could be obtained.

The obstetrician thought that there was probably birth injury despite the easy, normal labor, and nothing but the mildest supportive treatment was advised. There was no family history of epilepsy. The recovery from each attack was more rapid than is usual in epilepsy and the attacks were more frequent. A careful examination revealed a full term, large boned, but terribly emaciated and feeble infant with every evidence of marked nutritional disturbance, showing every symptom and sign of tetany with the development of convulsions typical of the spasmophilic diathesis.

As the infant seemed about to die, I felt that the therapeutic test could not be delayed. The response was even more dramatic than hoped for. Six hours after treatment was started, laryngospasm had practically ceased and in fifteen hours the convulsions had entirely ceased.

The treatment consisted of calcium chloride, 7 grains (0.45 Gm.), every hour; viosterol, 3 drops every two hours; phenobarbital, one-twelfth grain (0.005 Gm.), every four hours. Forced feedings, 1 ounce of breast milk, every hour, were administered with a medicine dropper. It took forty-five minutes out of every hour to get the ounce down. In twenty-four hours the calcium chloride was stopped as it produced vomiting. The phenobarbital was stopped in forty-eight hours.

2. Hess, A. F.: Rickets, Osteomalacia and Tetany, Philadelphia, Lea & Febiger, 1929.

In ten days the baby became a simple feeding problem and has developed so far into a perfectly healthy normal 12 months old baby.

Abt states that "in convulsions of the new-born, the diagnosis of cerebral hemorrhage is more frequently made than is warranted. When autopsy is systematically done, we are very often surprised at the frequent absence of cerebral hemorrhage in cases diagnosed as such." I can recall a few fatal cases of convulsions of the new-born diagnosed as birth trauma that well might have been diagnosed as tetany and treated as such.

SUMMARY

Tetany should be considered in all cases of birth injury with convulsions. It is suggested that the condition is really not rare.

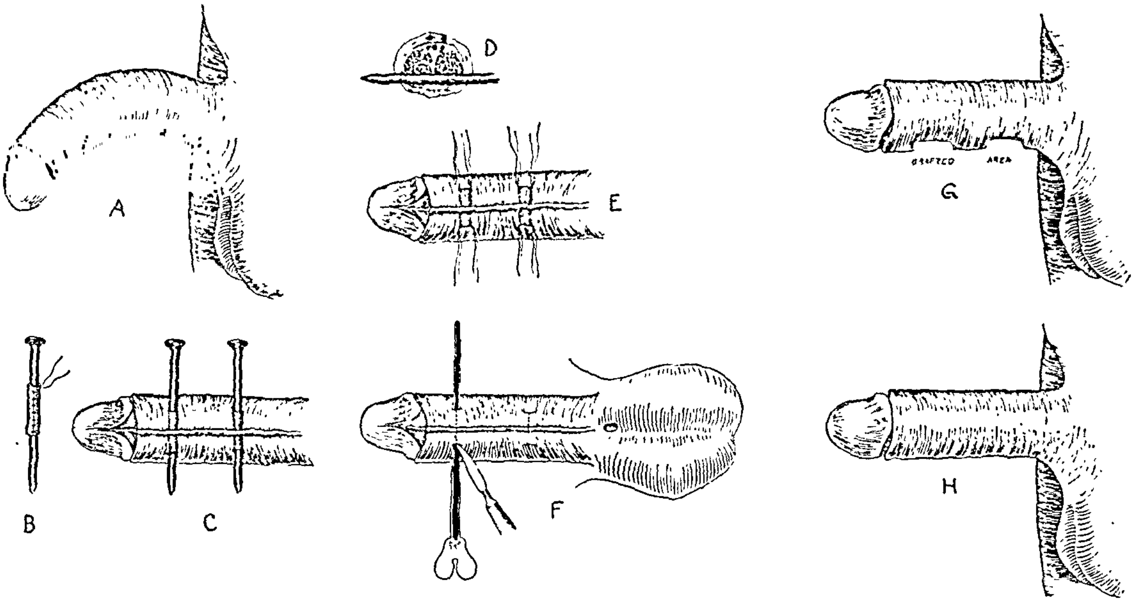
A therapeutic test is indicated in all questionable cases. Delay for positive diagnosis is desirable but dangerous.

The case reported here was cured with simple methods and drugs available to all practitioners.

A NEW METHOD FOR STRAIGHTENING THE PENIS IN HYPOSPADIAS

FRANCIS R. HAGNER, M.D., WASHINGTON, D. C.
Professor of Genito-Urinary Surgery, George Washington University Medical School

The incurvation of the penis in hypospadias is caused by the shortening of the fibrous tissue which in this malformation replaces the corpus spongiosum. There is always in this location a firm fibrous band which, because it is nondistensible, causes the chordee.



Method of procedure: *A*, location of puncture through corpora cavernosa for the reception of grafts; punctures are placed above the fibrous tissue that causes the chordee. *B*, tunneled graft. *C*, puncture through corpora cavernosa for reception of grafts. *D*, transverse section, showing location of puncture for reception of tunneled graft. *E*, grafts in place, held by sutures. *F*, cutting through the healed tunneled graft. *G*, result following incision of tunneled graft. *H*, ultimate result, from three to four months after operation.

A number of plastic operations—some of them more or less successful—have been devised for straightening the penis. But the weak point in all of them is the tendency to reformation of scar tissue at the seat of operation—in many cases this scar tissue causing a return of the chordee after the wound heals.

I believe that the method here explained offers the best solution of the problem. By this method the grafts, when healing occurs, take the place of the scar tissue that in a greater or less degree forms in all plastic operations.

More than a year ago I heard Colonel Kellar, at Walter Reed Hospital, read a paper on the use of tunnel grafts to overcome cicatricial contractures in other portions of the body. Noting his excellent results, I at once concluded that the use of this graft was the solution in overcoming the contracture and consequent incurvation in hypospadias.

I have followed almost identically his technic. The operation is performed as follows:

A graft, including all the layers of the skin, is cut from the inner side of the thigh and placed in salt solution. A cannula is then thrust through the corpora cavernosa, care being taken to place it above the line of the fibrous tissue that causes the chordee. The cannula that I use is a 17 French, but the size can be varied to accord with that of the penis. After the cannula is inserted, a back-and-forward motion is made to enlarge the puncture wound. The cannula is then withdrawn; the skin graft, previously mentioned, is placed around it—the skin side next to the instrument—and two or three fine catgut sutures are used to bring the edges together. The cannula carrying the graft is then reintroduced through the puncture and the graft is slipped off, two fine catgut sutures being placed at the ends to hold it in position. Two of these grafts are usually sufficient—a succeeding one, if necessary, being placed in the same manner, and the punctures being made about 2 cm. apart. The urine is drained by a retention catheter in the opening of the perineal or the scrotal urethra, and a sterile dressing is then applied.

Rapid healing of the grafts takes place. At the end of two or three weeks a grooved director is passed through the graft and incised from within outward to the surface of the skin. Slight bleeding occurs, but it can readily be controlled by pressure. The graft tends to flatten out as soon as the incision is made, but after a month or six weeks the grafted area can be noticed only by the difference in the appearance of the skin, while palpation at the base of the graft shows no tendency to the formation of scar tissue.

In no mode of straightening the penis before performing a plastic operation to make the urethra have I observed such results as occur when the procedure here outlined is followed.

Origin of Syphilis.—Somewhere and at some time a nonpathogenic spiral organism acquired pathogenic properties and became Spirochaeta pallida. It seems likely that this event took place in America, less than 10,000 years ago. . . . An antiquity for syphilis as slight as even 2,000 years would, I think, present no difficulties to a modern bacteriologist accustomed to the development of rough and smooth, nonvirulent and virulent colonies from one pure culture of bacteria, frequently under conditions that he can easily control.—Williams, H. U.: The Origin and Antiquity of Syphilis: The Evidence from Diseased Bones, *Arch. Path.* **13**:979 (June) 1932.

THE CHANGING DIET OF THE AMERICAN PEOPLE

LAFAYETTE B. MENDEL, PH.D., Sc.D.
Sterling Professor of Physiological Chemistry in Yale University
NEW HAVEN, CONN.

The study of anthropology leaves no doubt of the existence of epochs in the evolution of our diet. For the preparation of food, primitive races still use methods that must have been in vogue before the era of cookery. Sun drying, grinding, burying and maceration are ancient devices for rendering edible products more palatable and digestible. Some writers have depicted the happy dietary lot of early man living in a delightful climate in the midst of nature's utmost luxuriance. "The reality," Fitch[1] remarks, "was far from this Utopian conception, which was a product of a vivid imagination. The food which he was able to obtain easily was scarcely worth gathering, and in order to satisfy the pangs of hunger and to sustain existence, he was compelled to put himself to much trouble and to undergo many dangers. This is known from the fact that certain races, whose mode of life approximates most closely that of the primitive dwellers on earth, have the greatest difficulty in eking out a miserable existence."

The development of agriculture, including the cultivation of the soil and the domestication of animals, furnished many new possibilities for the production and selection of foods derived from animals as well as from plants. The progress of cibiculture and the introduction of cookery gradually brought about long ago what has been described as "the acme of dietary excellence." Such assertions therefore raise the question as to whether our present-day diets are really changing in any fundamental way.

Recently my attention was called to "A Treatise of Foods,"[2] published at the beginning of the eighteenth century by Louis Lemery. In the preface to this interesting volume the French scientist remarks that "if foods contribute so necessarily, to the preservation of life and health; they also produce the greatest part of those distempers, to which we are subject, and many times, by the ill use of them, cause even death itself." He adds that "the ground-work of our preservation, consists chiefly in a knowledge of suiting foods to every constitution, as it best agrees with it." And he concludes with the admonition that "the knowledge we ought to be most desirous of, should be that of foods."

A mere glance at the chapter headings of Lemery's book reveals an unexpected variety of all sorts of foods, of both animal and vegetable origin, together with a formidable list of condiments and "drinkables." One's first impulse on examining the volume is to ask whether we really have changed our dietary habits, inasmuch as our predecessors of two centuries ago could present such a diversity of items familiar in today's menus. The most conspicuous omissions in the older lists involved the more refined or processed edible materials that have been developed through the efforts of the food industries in the last few decades. This is notably true, for example, of the numerous highly milled cereal products and other cereal novelties that have come to take a conspicuous place in the American meals of today. Bread—the "staff of life"—no longer retains its supreme dominance.

The diet of a group may change not merely through innovations in the foods used but also because of revisions in the choice of long familiar edible products. This may result in a shift in the proportions of the true nutrients—the proteins, fats and carbohydrates—as well as in altered preferences with respect to vitamin-bearing foods. Have there really been noteworthy changes in our national dietary? Are there "styles" in food? Perhaps the easiest way to begin the solution of these questions is to examine a few characteristic menus of the past.

Our forefathers were not unaccustomed to lavish meals. In "The Accomplisht Cook, or the Art and Mystery of Cookery," printed in 1678, there are bills of fare for every month of the year. Let me present some details of a menu for All-Saints Day in November. The first course alone includes twenty dishes, beginning with oysters, continuing through beef and capons and geese and ducks and mutton, venison and swans, veal and roast turkey, and ending with "a double-bordered custard." The second course includes twenty more dishes—oranges and lemons, and more meat dishes—pig and lamb and ducks, "a couple of pheasants," several varieties of fish, three brace of partridge, and then a dish of spinach. After the spinach, a roll of beef, a cold goose pie, and so on and so on until we finally reach the dessert—jellies and tarts and gingerbread, "and other fruits," according to the original bill of fare. Is it any wonder, a reviewer remarks, that the old cookbooks included a few chapters on medicines and salves, and "broths for the sick"?

In Mrs. Glass's Cook Book, published in 1805, one of the dinner menus to be served in three courses contained the following offerings:

First Course.—Vermicelli soup, leg of lamb, chicken and veal pie, tongue, petit patties, cod's head patties, boiled chickens, roasted beef, scotch-collops.

Second Course.—Marinated smelts, roast sweetbreads, almond tort, roasted turkey, stands of jellies, maids of honour, woodcocks, mince pies, larks, lobsters.

Third Course.—Artichoke bottoms, custards, scalloped oysters, morels, dutch beef scraped, cut-pastry, potted chars, rabbit-fricasseed, macaroni, black cup, stewed celery.

The bill of fare of the Irving House in San Francisco for a banquet on Dec. 6, 1851, lists eighty dishes. There were two choices of soup, two of fish, twelve "National Dishes" (meats), six boiled dishes (meats), four roasts, six *hors d'oeuvres,* twelve entrées (meats), ten vegetables, ten game dishes, eighteen pastries and entremets (pies, puddings, cakes), and ten fruits and nuts as desserts.

In a volume on "The Sabbath in Puritan New England," Alice Morse Earle has given a description of the supper served on the occasion of the ordination of a new pastor of the Old South Church in Boston in February, 1861:[3]

> There were six tables that held one with another eighteen persons each, upon each table a good rich plumb pudding, a dish of boil'd pork and fowls, and a corned leg of pork with

> sauce proper for it, a leg of bacon, a piece of alamode beef, a leg of mutton with caper sauce, a roast line of veal, a roast turkey, a venison pastee, besides chess cakes and tarts, cheese and butter. They had plenty of old cyder, one barrel of Lisbon wine, punch in plenty before and after dinner, made of old Barbados spirit.

One of the early novels of Anthony Trollope, published in 1855,[4] describes the "breakfast-parlour" of a representative well-to-do clergyman. After discoursing about the breakfast service with its varied items of silver and china, the author referred to the viands as follows:

> The tea consumed was the very best, the coffee the very blackest, the cream the very thickest; there was dry toast and buttered toast, muffins and crumpets; hot bread and cold bread, white bread and brown bread, homemade bread and bakers' bread, wheaten bread and oaten bread, and if there be other breads than these, they were there; there were eggs in napkins, and crispy bits of bacon under silver covers; and there were little fishes in a little box, and devilled kidneys frizzling on a hot-water dish; which, by-the-by, were placed closely contiguous to the plate of the worthy archdeacon himself. Over and above this, on a snow-white napkin, spread upon the sideboard, was a huge ham and a huge sirloin; the latter having laden the dinner table on the previous evening. Such was the ordinary fare at Plumstead Episcopi.

The conditions represented by this description were not fundamentally different on this side of the Atlantic. In Robert Playfair's Recollections of a Visit to the United States[5] in 1847, 1848 and 1849 he refers to the food that he encountered in the hotels, in these words:

> Printed bills of fare were placed within reach of each guest, so that we might select what we pleased, nor did I observe any symptom of the rapid eating some tourists have described.
>
> As this dinner is a type of what is generally found throughout the Union at the best hotels, I here insert a Bill of Fare during my stay at the City Hotel, which may not be uninteresting to my English reader: the impression probably will be that these Republicans live well.

Then follows the table d'hote menu for Sunday, Aug. 8, 1847. The "first course" offered along with soup and fish (broiled fresh salmon, lobster sauce), boiled turkeys, oyster sauce, boiled rump corned beef and cabbage, boiled sugar cured ham, boiled lobster salad, boiled beef tongues, stewed kidneys with wine, macaroni with Parmesian cheese, sweetbreads with sorrel, broiled chickens with bread, stewed ducks with olives, stewed pigeons with mushrooms, fillets of fresh pork with tomato sauce. To these were added entrées as follows: poitrine de mouton, grillé, à la sauce tomate; fricandeau, à la sauce tomate; canard, braizé, aux navets; tête de veau, à la sauce tomate; huitres à la poulette; côtelettes de mouton, en papillote; pâtés de poulet; poitrine de veau, aux champignons; blanquette de veau, au currie; salmis de bigier; bifstek auz huitres; roast tame geese, apple sauce; roast young chickens; roast tame ducks; roast sirloin of beef; roast lamb, mint sauce; roast veal, roast pig, pickle sauce; squash, green corn, tomatoes, beans. A "second course" consisted of game; roast yellow-leg snipe. The "third course" included only three items of pastry; namely, ice cream and pies. The "fourth course" was devoted to dessert: almonds, watermelons, blackberries and raisins.

These are, of course, records of the best food afforded by institutions that catered to the well-to-do. In the letters of Thomas Mooney, published in 1850 under the title "Nine Years in America," it is related that "the food of the American farmer, mechanic, or labourer, is the best . . . enjoyed by any similar classes in the whole world. At every meal there is meat or fish or both. . . . The breakfast of the common people is made up of coffee or tea, fish, meat, butter, bread, potatoes, all on the table." Dinner included tea, meat, bread, hot cakes and the like.

One is impressed, in surveying such menus, by the great abundance of flesh foods in the dietary. This is true regardless of the time of day when the meals were served. The supply of muscle meats was evidently more readily maintained throughout most seasons of the year than was that of fresh fruits and vegetables. With the passing of the years there has been a gradual displacement of meats from their former dominance in the regimen. The modern statistics of the food industries indicate an increased consumption of dairy products, vegetables and sugar.

The story of sugar is particularly interesting.[6] During the early part of the last century, sugar was used primarily as a condiment. The consumption in 1823, for example, has been estimated as enough to give each person 8.8 pounds a year. This represents about 44 calories a day. Last year, somewhat more than a century later, the annual per capita consumption of sugar amounted to 108 pounds, or more than 500 calories a day. This means that sugar has become an important food, representing, on the average, nearly one sixth of our energy intake. Incidentally, this has been accomplished with a tremendous reduction in the cost of the product; 1,000 calories are being sold at a retail price of less than 3 cents.

Obviously, this change in food habits in the case of sugar has resulted in the displacement of other foods from the national diet. As I have stated elsewhere,[6]

> The fact that one fifth of our diet, nowadays, consists of this vitamin-free food is especially important because the other four fifths have also lost much of their vitamin potencies in the refining processes to which so many modern foods are subjected. Cornstarch, for instance, is a purified food; the *vitamins and salts of the maize kernels from which it is made* have been taken out. Rice, in the process of polishing, has lost most of its vitamins, and the same is true of other highly milled cereals. And not only the carbohydrate foods but also the fats and even some of the proteins in our diet are being subjected to chemical "purification" before they reach our kitchens.

The tendency toward the displacement of meat dishes, with their higher protein content, is indicated in the recent experience of American restaurants that have adopted the new fixed-price plan with the slogan of "all-you-can-eat." This means that the patron may repeat orders for any dish on the menu without added expense. An observer[7] has remarked that thus for the first time there has been a large-scale popularity contest, with no price handicaps. She further comments: "The result of the wide-open menu has not been vast new inroads on the roast beef and the mutton chops and other stalwart he-man viands." She then adds: "What we lean, dieting, strenuous go-getters of Yankees really want—according to the past year's comprehensive experiment—is more dessert! Our erstwhile suppressed desires have apparently been for ice cream on our apple pie, more peach shortcake and another chocolate eclair."

[7] Barnard, Eunice Fuller: New York Times Magazine, Feb. 28, 1932.

There are more objective indications of changes in our food preferences in the direction of lessened protein intake, such as a decrease in meat consumption would bring about. In the course of a long experience as a teacher of metabolism I have gathered the reports of hundreds of analyses of twenty-four hour urines of young men and women. In health the nitrogen content of the kidney output furnishes a reliable index of the nitrogenous (or protein) intake. During the nineties of the last century the estimated protein intake, after due allowance for fecal losses of nitrogen, generally approximated an average of at least 100 Gm. (16 Gm. N × 6.25) a day. In the course of the years, these annually secured estimates are showing lower averages. Other teachers have had similar experiences. The newest figures of Hetler[8] on young women in Illinois studied during the years 1928-1930 averaged 7.7 Gm. of nitrogen (equivalent to about 50 Gm. of protein metabolized) daily. This corresponds to 9.5 Gm. of nitrogen (or about 60 Gm. of protein) for a man weighing 70 Kg.

How have these changes in our food habits come about? Are they merely the result of our instincts? Several years ago my colleague T. B. Osborne wrote:

> Under normal conditions of supply and normal conditions of health, little attention is given by the great mass of mankind to the question what or how much should be eaten. They simply eat what they want and as much as they want, and then stop and go about other business. They know nothing of the dietary elements which the nutrition expert tells them are so essential for their well being, and even for their very existence.
>
> How can they long survive in such ignorance? Why does the community allow them to endanger, not only their own lives, but those of posterity? The only possible answer is that they are endowed with instincts which guide them so well, that under normal conditions of life they escape the many dangers that until recently they were unconscious of.

Instinct, which was long lauded as the safe guide to ideal nutrition and which is still heralded even by physicians, has been shown to have its definite limitations in the choice of foods by man. A generation ago Ellen H. Richards, an American pioneer who exhibited zeal for the application of science to daily life, wrote:

> It is unsafe to trust the individual to the guidance of the appetite alone, for the reason that this instinct was built up for a condition of existence very different from that which enables the people of this country to indulge themselves today.

Realizing the effect that changes in the transportation and distribution of commodities were exerting on the availability of the food supply, she sensed "conformity to scientific laws as the only way to safety."

In an address before the Second Pan American Congress in Washington, in 1916, I[9] remarked that

> The supply of food energy and its availability where needed are interrelated closely with a variety of factors, the bearing of which upon the problem at hand is not always evident upon the surface. Some of these features may be classified superficially as follows:
>
> 1. Food production.
> 2. Food preservation and food conservation.
> 3. Transportation facilities.
> 4. Customs in diet.
> 5. Changing industrial and social conditions and other economic and hygienic factors.

It is possible today to secure fresh meats, fresh eggs and fresh milk in every urban center without interruption; citrus fruits and some sorts of fresh vegetables are available throughout the entire year, even in the smallest hamlet. The opportunity of selection has thus become greatly enhanced. To these important changing factors must be added the results of research in the physiology of nutrition and the extension of popular education regarding foods and diet.

As far as the medical profession is primarily concerned, our modern knowledge has served to establish firmly the calory idea in nutrition. The advantages of intelligent "calory feeding" in infancy and the so-called high calory diets in certain types of prolonged fever, notably as advised by Coleman in typhoid, have become permanent accessions to medical practice. Newburgh has lately demonstrated anew that the successful management of obesity is fundamentally a problem of energy bookkeeping, of balance between intake and output, regardless of the existence of long periods of stationary body weight due to retention of water.

The growing information about the formerly unsuspected dietary essentials called vitamins has begun to afford intelligent appreciation where obscurity formerly prevailed; it has also permitted new interpretations of long suspected nutrient virtues in foods. The red tomato served on a green lettuce leaf can no longer be dismissed as merely an esthetic combination of water, roughage and inorganic salts. The golden citrus fruits supply something more than the tart sweetness of their palatable juices. Milk and butter have become more than rich sources of energy. Cod liver oil or concentrates thereof are being widely used as prophylactics. Salad greens are eagerly ordered and eaten. Our population is becoming "vitamin-conscious."

The discovery, in 1895, of iodine in the body, its relation to thyroid function, and its variable sources in nature, ushered in a new era of interest in "the little things" in nutrition. A few milligrams—less than a single grain—of a long recognized element spell physiologic well being that turns to disorder in their absence. The rôle and importance of calcium and phosphorus and chlorine are being elucidated more clearly every year. Copper has become an additional hematopoietic possibility where iron once reigned alone. Manganese beckons with possibilities. The inorganic elements are no longer neglected in relation to nutritive welfare. "During the past ten years," Mary Swartz Rose[10] recently wrote, "we have gradually become accustomed to thinking quantitatively in nutrition, not only in terms of calories and grams of proteins, fats and carbohydrates, but in terms of fractions of milligrams of mineral elements and vitamins." The potential acidity and alkalinity of our foods are attracting attention—perhaps even more than they deserve. In any event the physician ventures nowadays to conjure with foods as he has always done with drugs.

With the advent of modern bacteriology came the brilliant demonstrations of the specific microbiotic origins of many long known maladies of previously obscure etiology. Soon it became a natural tendency to postulate bacterial causes for every puzzling disease.

Scurvy and beriberi were considered from this standpoint by more than one investigator. Little progress was made in the control of these disorders. With the growth of the newer knowledge of nutrition, however, has come the almost complete disappearance of scurvy in this country. There was a time when it seemed like a plague. It infested armies; it decimated those who traveled the seas; it put an end to more than one expedition into remote regions. In the first edition of Osler's Modern Medicine, published in 1907, scurvy was still classed with the nondescript group of "constitutional" diseases, including diabetes and gout. One can understand better what the present-day dietary management of scurvy and the prophylaxis against a once common disorder of man means by reading the views of the best writers of only twenty-five years ago. Thus, Robert Hutchison[11] wrote in the volume referred to:

> Summing up all the evidence, it seems probable that whilst a deficiency of fresh vegetables, i. e., of organic salts of potash, plays a part in the production of the disease by reducing the alkalinity of the blood, yet this does not afford a complete explanation of the occurrence of all the symptoms, and it is not unlikely that upon the soil so prepared there is grafted some specific infection which finds access to the body by the mouth. Insanitary surroundings, overwork, mental depression, and exposure to cold and damp, facilitate the development of the disease by lowering the resistance of the patient.

Today it can be said, in the words of A. F. Hess:[12]

> There is almost nothing in the realm of therapy which is so striking as a scorbutic patient's prompt reaction to antiscorbutic treatment. It is all the more marvelous as the cure is effected by means of foodstuffs with which we are accustomed to associate no specific virtue. A magic result is seen frequently within twenty-four or forty-eight hours. A baby which has had a poor appetite, has been irritable and exquisitely tender, suddenly regains its appetite, is no longer fretful, and can be handled without occasioning crying. Within a week, if the case is mild, all definite symptoms of scurvy may have disappeared, and soon thereafter the infant is thriving and apparently cured.

This is the story of the effectiveness of a food constituent, vitamin C, of which the production, in the laboratory of the organic chemist, seems imminent.

The etiology of rickets also is now better understood and its dietotherapy appreciated. The circumstance that rickets still remains so widely prevalent is perhaps a serious criticism of the medical profession and a challenge to its resourcefulness in the use of available curative and prophylactic agents.

Despite some doubts voiced now and then as to the precise etiologic background of both beriberi and pellagra in man, there are growing evidences that they belong primarily among the avitaminoses and can be averted by proper diet. Some of the practical difficulties may be attributable to the possibility that the clinical manifestations represent syndromes in which more than one dietary deficiency is involved. McLester[13] has recently asserted that the interest which vitamins hold for the physician is not alone in their relation to certain well defined diseases such as scurvy, beriberi and rickets, but rather in the fact that chronic vitamin deficiency produces numerous vague, borderline states of ill health which often puzzle the physician and disable the patient. These last are of far greater importance to the physician of today than the more clearly defined deficiency diseases.

The possibilities of accelerating or retarding growth through dietary measures alone have been indicated again and again in recent years in the experimental laboratories. Some of the discoveries have begun to be applied in human dietetics. The greater use of so-called protective foods, including fruits and vegetables, has become widespread. The insistent propaganda for the more liberal inclusion of milk in the regimen of the old as well as the young is finding acceptance. It is too early to determine the possible effects of some of the changing food habits through which in turn meats and then the cereals have lost some of their former dominant popularity. There are signs that many of our adolescents are growing somewhat more rapidly than in former generations. Is this an outcome of our modern education and advertising? Is it a wholesome trend? It is too early to answer these questions with conviction; but our menus have indeed changed.

There is no field of practical importance related to human well being in which there is greater opportunity for dogmatism and quackery, for pseudoscience and unwarranted prescriptions and proscriptions, than in the domain of our daily diet. Those who have seen the pendulum of enthusiasm swing from one extreme food fad to another in the course of the years will be wary. Let them keep an open mind, without becoming too reactionary to notice that our food habits do change.

CLINICAL ASPECTS OF VITAMIN G DEFICIENCY

FRANK P. UNDERHILL, Ph.D.
NEW HAVEN, CONN.

[Editorial Note.—The following article is one of a series on the Present Status of the Knowledge of Vitamins, prepared under the auspices of a committee composed of Morris Fishbein, chairman, Lafayette B. Mendel and Julius Hess, representing a joint committee of the Council on Pharmacy and Chemistry and the Committee on Foods. These articles have been considered by the Council on Pharmacy and Chemistry and by the Committee on Foods and are published under their auspices. The opinions expressed are those of the authors and not necessarily the opinions of the Council on Pharmacy and Chemistry or the Committee on Foods.]

It is the prevalent opinion that vitamin G deficiency is intimately associated with the complex syndrome of symptoms included under the term pellagra. The complexity of the disease is so evident that some reluctance is justified in accepting the view that a single food deficiency may be responsible for such a varied series of clinical manifestations. In fact, some writers have suggested that what is called pellagra may be a mixture of diseases rather than an entity,[1] for in a given patient pellagra may involve predominantly only one system, whether this is the skin, alimentary tract or nervous system, and little damage may be done to the other systems;[2] on the other hand, all three systems may be affected. Again, the symptoms observed may be so atypical of the classic features of pellagra that they have received the name pellagra sine pellagra. At the present stage of knowledge one may accept the view that, although vitamin G deficiency is closely

related to pellagra, some caution must be exercised in relying on this vitamin deficiency as being entirely responsible for the etiology of the disease. This caution is especially pertinent when preventive or curative measures are to be advocated. The discovery of the potency of the unknown factor termed vitamin G is an undoubted advance in the knowledge of pellagra, but it is clearly unwise to assume that vitamin G deficiency and pellagra are necessarily synonymous terms. In view of the experimental data available, there appears the possibility that there may be several deficiencies involved in the disease condition under discussion.

It is significant that the earliest records of pellagra are associated with a food factor. It was in 1600 that Barnino described the occurrence among certain Indian tribes in America of a disease answering to the description of pellagra, which he related to maize. Since the time of Barnino the consumption of maize and the incidence of pellagra have been closely associated. As expressed by a writer in 1917, "to weave a chronicle of pellagra without encountering the visage of maize seems almost impossible. Through the tangled skein, as it is interwoven with the destinies of several nations and peoples, we see the rise and decline of this malady almost coincident with the consumption of Indian corn, and try as we may we cannot dissociate the two."[3] The view that corn bears a specific relationship to the etiology of pellagra has been hard to eradicate, but gradually opinion has changed so that other food factors are included. In the words of Goldberger,[4] "the consumption of corn or corn products is not essential to the production of pellagra, but this does not mean that corn, the best of corn, or corn products, however nutritious or however high in caloric value they may be, are not objectionable when forming of themselves, or in combination with other cereals and with vegetables, a large part of the diet of the individual."

In latter days the conception of the factor involved in the production of pellagra has undergone a radical change. When maize was specifically related to the disease it was assumed that this cereal played its rôle by imparting a noxious agent to the dietary, a toxic substance, produced possibly by a chemical change in the process of "spoiling." As early as 1776, Venice passed legislative measures to prohibit the sale or exchange of ill smelling, ill tasting, or discolored corn. Opposed to the older view that corn causes an intoxication stands the present-day hypothesis that corn and certain other foodstuffs lack something essential to proper nutritional rhythm; in other words, they are deficient.

It must not be accepted that food factors only have been assumed to bear a causal relationship to pellagra. Such is far from the fact. From time to time points of view have been presented which included infection carried by winged insects of blood sucking habits; infection of unknown origin, and infection carried by water containing silica or aluminum. The hypothesis of infection with a living micro-organism of unknown nature has many arguments to recommend it. MacNeal,[5] who is opposed to the food deficiency theory, believes that

> the etiology of pellagra depends on two factors analogous to those recognized by Roussel: (1) the specific causative factor which is a living organism, an infectious agent derived directly or indirectly from a previous case of the disease, and (2) a factor or group of factors, quite nonspecific, which serve to reduce the resistance of the victim. In this latter group are recognized malnutrition, either from inadequate food or inability to utilize food in an adequate manner, cachexia of disease, overwork, depressing influence of hot weather, strain of reproduction in women, involution of old age, alcoholism, and many other influences. The specific causative, which I believe to be a living organism, remains unrecognized. Most probably it remains in the gastro-intestinal tract, and the absorption of its products from the digestive tract gives rise to the distant manifestations of pellagra. In regard to the factors influencing the possible transmission of the hypothetical parasite, as well as those which may influence the resistance of the human individual, a great many facts have become established by epidemiologic studies in pellagrous districts.

Plausible and convincing as the infectious theory may appear, current opinion inclines to the view that if infection plays a rôle in pellagra it is of secondary importance and not causative. Much more significant are the factors that MacNeal terms nonspecific.

The incidence of pellagra is widespread. Every nation of Europe, including England, has had its experience with pellagra. In general, however, the disease has made less headway in the countries of the temperate zones than in those of warmer climates. It was not until 1863 that the disease was first clearly described in the United States. The high mortality in certain of the Southern prison camps during the Civil War has been ascribed to this disease. Since this period, pellagra has gained great headway in this country, especially in the Southern states, until today it is quite as prevalent as in Europe, if not more so. It seems quite inexplicable that in the United States, where so much has been contributed to the knowledge of nutrition, especially to the knowledge of vitamins, and where principles of nutrition have been so popularized that nearly every one has a speaking acquaintance with foods and food values, a disease presumably essentially related to food maladjustment should become so prevalent and should be decidedly on the increase. The situation is becoming relatively acute.

That diet plays the predominant rôle in the production or prevention of pellagra was first clearly established through the investigations of Goldberger and his associates. It was demonstrated by Goldberger, Waring and Willets[6] in 1915 that clinical recovery is obtained by proper feeding and is maintained as long as proper diet is continued. The dreaded recurrence of the disease does not take place in individuals receiving adequate nourishment. According to these authors there is no good evidence that the disease can be prevented by any other means. Having established that the disease may be prevented by proper diet, Goldberger and his associates[7] next attempted to induce the disease by selection of what they considered a diet resembling that found associated with a high incidence of pellagra in earlier studies. In this investigation six of eleven subjects developed the disease, whereas none of the control subjects evinced any symptoms.

The food factor responsible for the production of pellagra was at first associated by Goldberger and Tanner[8] with the amino-acid content of the proteins included in the diet. It was concluded that the essential etiologic dietary factor is a specific defect in the amino-acid supply, probably in the nature of a deficiency of a special combination or combinations of amino-acids. On this hypothesis, an investigation of the therapeutic and preventive value of casein was undertaken. In 1925, Goldberger and Tanner[9] reported that while the casein had had a beneficial effect on the general nutrition of their patients and in considerable measure prevented or, at least, notably delayed the development of the distinctive eruption, it did not prevent, though it may have delayed, the relapse or recurrence of some of the other symptoms of the disease. They concluded, therefore, that the protein factor, if it is concerned in pellagra, is not the sole preventive or causative factor and thus that some heretofore unrecognized or unappreciated dietary complex also plays an essential rôle.

In an endeavor to discover the identity of this unknown essential complex they found that dried yeast is very effective in preventing the disease and that lean beef[10] also contains the effective agent, which was designated P-P (pellagra preventive). Further investigation revealed the fact that the P-P factor is associated with that earlier known vitamin "water soluble B," which had been assumed to possess only antineuritic properties. By means of heat, the antineuritic properties of yeast are destroyed, leaving a fraction which is pellagra preventive and apparently identical with Goldberger's P-P factor. The heat resistant pellagra preventing factor has been termed vitamin G.

The foregoing recital would lead one to infer that the conclusions of Goldberger and his associates were derived entirely from experiments on the human pellagrous subject. Such a view would be erroneous, for a perusal of the literature soon convinces one that the main inferences derived were first obtained through experiments on the dog. The dog, as a possible experimental animal for the study of pellagra, first came into prominence through a report which Chittenden and I[11] made concerning the production of a pathologic condition that bore certain resemblances to human pellagra. We ascribed the development of the disease to a deficiency of some essential constituent or constituents, presumably belonging to the group of hitherto unrecognized but essential components of an adequate diet. Five years later Wheeler, Goldberger and Blacklock[12] identified this experimental condition with the spontaneously occurring disease of dogs known as black tongue. Attention was also called to the strikingly similar geographic distribution of the two conditions in the United States, pointing out that black tongue, like pellagra, seems to occur for the most part in the Southern states. Goldberger and Wheeler[13] were able to reproduce in dogs an experimental condition similar, at least, to that which Chittenden and I produced, which Goldberger and Wheeler regarded as experimental pellagra. The symptoms were induced in dogs by a type of diet found to be associated with the occurrence of pellagra and also with a diet that had produced pellagra in the human subject.

Mendel and I[14] continued the investigation which Chittenden and I began and recently published an elaborate report. It is shown here that when butter fat is fed to dogs suffering from the deficiency disease which Chittenden and I described, those animals are quickly restored to a normal condition and may be maintained in health for long periods. Under similar circumstances cod liver oil, known to contain active fat-soluble vitamin A, fails to restore these diseased dogs. Evidently this vitamin is not the potent factor in butter fat. The effective factor in butter fat is apparently quite labile, for the potency is diminished by maintenance in cold storage during a period of from nine to eleven months. The presence of the potent factor in butter fat is associated with the color of the butter. As the color decreases, the potency is diminished. Egg yolk contains the effective factor but is apparently less potent than butter fat. It would appear that there is a direct relationship between the presence of carotenoids in the substances listed and the potent factor. This is supported by the fact that crystallized carotene in relatively small doses is capable of curing the disease condition. These authors also call attention to the possibility that naturally occurring pigmentary substances in foodstuffs may play a rôle in nutritive processes.[15] In connection with the last statement it may be recalled that this was written before it had been shown that carotene is closely allied to, or a possible precursor of, vitamin A.[16]

On the other hand, Goldberger and his associates[10] find that butter and cod liver oil exhibit little potency against black tongue or human pellagra. In black tongue as well as in human pellagra, yeast, yeast extract and fresh lean beef possess preventive powers. They have also extended their studies to include the rat as an animal capable of serving as an experimental subject for the production of pellagra.[17] Attention is also called to a study of the black tongue preventive action of sixteen foodstuffs including maize, whole wheat, wheat germ, cowpea, soy bean, milk, butter, cod liver oil, cottonseed oil, beef muscle, pork liver, canned salmon, egg yolk, canned tomatoes, carrots and rutabaga turnips. Of these substances, liver, salmon and egg yolk are rich in black tongue preventive and are recommended for use in the treatment and prevention of pellagra in man. The other substances may contain small amounts of the effective agent but in general are poor sources, with the exception of wheat germ and beef muscle.

At present there exists a wide discrepancy between the results which Mendel and I reported and those of Goldberger. The former found that butter, carrots and pig's liver were effective agents in the prevention of our experimental condition and that the pathologic symptoms developed in the presence of an apparently adequate supply of compressed yeast. On the other hand, Goldberger and his associates assert that butter and carrots are ineffective but that yeast, pig's liver and lean beef possess preventive powers against black tongue and human pellagra. The suggestion has been made by Goldberger[17] that the two experimental states under discussion may not be identical as had previously been assumed. The variations in experience with the experimental condition are perhaps only an expression of the complexity of the syndrome elicited and may be indicative of a multiple deficiency eliciting manifold symptoms which, although superficially alike in etiology, may be quite distinct and separate. Until further much more critical experimentation is completed, decision must be reserved relative to the identity of the two experimental pathologic states and their relationship to human pellagra. Aykroyd [18] has suggested that the Underhill and Mendel syndrome has its origin in vitamin A deficiency. This comment is hardly pertinent since the pathologic state may be induced when active cod liver oil is present in the diet, a fact which Aykroyd apparently overlooked.

[17] Goldberger, Joseph; Wheeler, G. A.; Lillie, R. D., and Rogers, L. M.: Pub. Health Rep. **41**: 1385 (Feb. 19) 1926.

An examination of Goldberger's experimental results leads to the conception that in his human subjects the outstanding symptoms were sore mouth and a dermatitis involving a restricted area, the scrotum; with the dog suffering from black tongue, the prominent features were sore mouth and dermatitis of the scrotum; and with the rat a symmetrical dermatitis and loss of hair, gastro-intestinal symptoms being less pronounced. In none of the different types of experimental subjects was there significant evidence of the involvement of the central nervous system—evidences of cord degeneration, for example. The importance of cord degeneration in the syndrome has perhaps been underemphasized. It certainly has been recognized as contributing to the many sided syndrome of pellagra, but its significance has not been fully appreciated. Vedder [19] has suggested that the skin lesions which are so characteristic of pellagra may be referable to changes in the cord. He asks, "Otherwise, how can we explain the marvelous symmetry that is practically the constant characteristic of this symptom?" Mellanby inclines to the view that pellagra may be the outcome of a double deficiency, the absence of vitamin G being responsible for the skin changes and a deficiency of vitamin A or carotene allowing nerve degeneration to develop. In the experimental animals of Mellanby, degeneration of the cord occurred in the presence of yeast and other sources of vitamin G. He was unable to induce degenerative changes in the cord by feeding yellow maize and indicates that this failure may be due to the fact that yellow maize contains carotene.

In pernicious anemia, cord degeneration also occurs. The blood changes in this condition are not cured by the fat soluble portion of the liver.[20] On the other hand, Ungley and Suzman [21] assert that the nerve symptoms of pernicious anemia can be greatly improved by feeding whole liver. The possible interrelationship in the etiology of pernicious anemia and pellagra thus becomes manifest. To befog the clarity of this issue comes the recent pronouncement of Goldberger and Sebrell [22] to the effect that Minot's liver extract has a very definite delaying effect on the occurrence of symptoms in dogs on a black-tongue producing diet and that, when fed to dogs in an attack of black tongue, it has a very definite curative influence. "In view of the evidence herein presented, it seems that Minot's liver extract is a fairly good source of the antipellagric vitamin, and given in larger quantity would be of value as a temporary expedient in the treatment of pellagra." It must be pointed out, however, that in all probability the agent in liver extract responsible for the curative action of the blood picture of pernicious anemia is not identical with vitamin G, for it has been indicated that the antipellagric vitamin is not responsible for the effectiveness of liver in pernicious anemia.[23]

It would appear from this review that the allocation of vitamin G as the sole factor in pellagra is not well established and that too much reliance should not be placed on this agent in the prophylaxis and treatment of pellagra. A period of more than five years has now elapsed since the promulgation of Goldberger as to the effectiveness of the antipellagric vitamin. From a large experience with the disease, Turner [24] has recently reviewed the situation in the following words:

> The spectacular success of certain specific remedies for parasitic diseases such as malaria inspired physicians to hope that specific remedies would follow naturally in the wake of discovery of specific etiology. Pessimism has long ago succeeded such rosy optimism. However, in the field of the deficiency diseases the old optimism largely holds. There is an assumption in the minds of many that the administration of adequate specific vitamin must be followed by prompt clinical cure of the particular deficiency disease. Certainly the results of therapy in scurvy and rickets give some justification for this faith. However, there is a growing realization that disease in humans is rarely due to one factor, as it often appears to be in experimental animals. Castle and his associates have brought forth most convincing evidence of the importance of factors peculiar to the patients' own physiology on the pathogenesis of pernicious anemia, which might with reason be called a deficiency disease.
>
> It is now five years since Goldberger and his colleagues announced their studies on the value of factor P-P (now called vitamin G or B_2) in preventing the relapse of cutaneous pellagra in a group of patients in the Milledgeville Hospital. These results have been accepted widely as establishing the identity of pellagra with certain syndromes produced in experimental animals, and as final proof that factor P-P is the cause of pellagra. During these years those of us who see pellagra frequently have seen a large percentage of patients either die or go into chronic illness [25] in spite of what appeared to be ample opportunity for vitamin therapy to have been effective. The rather poor showing of vitamin therapy in pellagra may be used either as argument against the specificity of vitamin G or it may be interpreted as indicating that changes have taken place due to pellagra or some other disease or constitutional state which makes the vitamin ineffective.

In all fairness to the concept of Goldberger as to the effectiveness of vitamin G in experimental black tongue or pellagra, it should be pointed out that the real significance of vitamin G is more likely to be accurately evaluated under his controlled conditions than is possible in clinical practice, in which all types and particularly all stages of the disease are encountered. It is hardly possible to expect that, when structural damage has proceeded to certain limits, vitamin G, or for that matter any therapeutic measure, is likely to restore structures injured and, consequently, the patient to normal physiologic rhythm. From my own experience on dogs with the so-called pellagrous condition resulting from a deficient diet, the fact has stood out clearly that it is much easier to prevent the appearance of symptoms than to cause them to disappear. On the other hand, at certain early stages of the disease the symptoms may be made to disappear by proper change in diet, and, so far as one may judge, the animal is restored to normality, which is maintained indefinitely so long as the nutrition is adequate. If, however, the disease is allowed to progress to stages beyond those mentioned, all efforts to restore the animal to health are useless and it invariably goes on to death.

[24] Turner, R. H.: A Physiologic Basis for the Treatment of Pellagra, read before the Section on Pharmacology and Therapeutics, at the Annual Session of the American Medical Association, Philadelphia, June 11, 1931.

[25] More than 30 per cent of certain large groups of hospital patients die. Chronic ill health following an attack is almost the rule.

From the theoretical point of view it would seem that vitamin G, so far as it plays a rôle in the syndrome of pellagra, may be of far more value as a prophylactic measure than as a curative agent.

Turner is quite aware of the influence of possible structural change on curative possibilities, as attested by his statement which follows:

> That extensive alimentary tract damage may occur in pellagra is well known, its extent and severity are extremely variable and have been inadequately studied by clinician and pathologist. It seems, then, probable that many of the therapeutic difficulties encountered in pellagra may be due to the existence of a vicious circle; malnutrition promoting alimentary tract damage and alimentary tract damage in turn interfering with nutrition. This concept would put chief emphasis for prognosis and therapy on the state of the alimentary tract. The evidence that alimentary tract damage predisposes to pellagra has been recently reviewed by Eusterman and O'Leary.[26]

The last mentioned authors consider that pellagra may be secondary to obstructing benign lesions or dysfunction of the upper part of the digestive tract. In these cases of interference with proper alimentation it is possible that parenteral administration of vitamins may be advisable when suitable preparations become available.

Bender[27] and Nuzum[28] have reported secondary pellagra under somewhat similar conditions, the only apparent cause being the interference in alimentation.

Just as pellagra may be induced by diminished food intake because of disease, so may it appear by voluntary restriction of diet. Pellagra is usually associated with the poorer classes of society in which, for economic reasons, adequate food supply is difficult to obtain. There is, however, abundant evidence that the symptoms of the disease may be manifested among individuals whose economic status includes them in the class of the wealthy. Roberts[29] has presented detailed records of twenty-five patients developing pellagra whose tables contained an abundance of well balanced food. Roberts shows that not one of these patients ate a well rounded diet of meat, milk, eggs or wholesome vegetables. He notes that the leanness of most of the patients was striking and remarks that fat people rarely become pellagrous. In this series of cases Roberts shows that his patients had the best food and that they fell into two groups: (*a*) One class ate an unbalanced diet; (*b*) the other ate not only an unbalanced but a "skimpy" starvation diet. These patients were undernourished. As soon as they were placed on a diet which they had formerly refused for psychic or imaginary reasons, they ate it continuously, improved and led active lives. "There is apparently among the better classes a small proportion who have a natural or acquired antipathy to a well rounded, balanced diet. Is there a dietary hysteria? Some persons pride themselves on never getting hungry. Grief, monotony, disease, domestic worries, the preparation of food, constipation are agents in depriving women more than men of their appetites. In this series there were only four men and twenty-one women." Tanner and Echols[30] have also called attention to similar cases.[28] Carley[31] reports a case of pellagra in a woman who, because of fear of cancer, voluntarily eliminated various articles of food until little else than cereals was being ingested.

That alcoholism may contribute its share in the onset of pellagra has been demonstrated by Klauder and Winkleman.[32] In these patients the history uniformly concerned alcoholism of years' duration, with symptoms of pellagra appearing after a debauch lasting for weeks, and often months, during which time incredible amounts of alcohol were consumed daily and little or no food eaten, or, at most, only one type of food.

Dietary restriction instituted to combat some other disease may in itself give rise to symptoms characteristic of pellagra. This is well illustrated in the treatment of epilepsy by the administration of a ketogenic diet. Guthrie[33] and Greer[34] have described cases of such nature, the symptoms disappearing on resumption of a more complete diet.

Finally, in this period of financial depression with the establishment of "bread lines" in many of the larger cities, pellagra may be expected to be encountered with increasing frequency unless measures are taken to provide against possible vitamin deficiencies in the food that is passed out.

That such a situation is already existent is attested by Dr. DuBois[35] in the following words:

> Three or four years ago in Bellevue we began to notice in the medical wards a few patients with symptoms of mild pellagra. These consisted in a beefy red tongue, persistent diarrhea and a roughness of the backs of the hands with a dark discoloration. This was not very marked and some of the dermatologists when they saw the skin lesions called them pseudopellagra, whatever that might be. Three years ago the only patients who presented this symptom complex were the lowest type of alcoholics who go for months living on bad whisky, coffee and doughnuts. At that time Dr. Feigin, who had charge of the alcoholic ward at Bellevue, told me that he was seeing many cases of mild pellagra.
>
> Last year we continued to find in our wards about the same number of alcoholics with mild pellagra but in addition we encountered a half a dozen or so cases which occurred in men who were not alcoholic, as far as we could judge from their histories and physical examination. Practically all, probably all of these mild pellagrins gave the story of many months without work, bread lines, cheap lodging houses. As far as I could tell, the food given out in the bread lines was deficient in calories and vitamins and second helpings were obtainable only if one waited a second period of three or four hours in the line.

W. W. COBLENTZ, Ph.D., D.Sc.
WASHINGTON, D. C.

Recently I[1] published the results of a survey of the question of the minimum intensity of ultraviolet radiation acceptable for therapeutic purposes.

Based on six major lines of evidence, I arrived at the conclusion that, in order to insure effective therapeutic results, the intensity (radiant flux density) from sources of heterogeneous ultraviolet radiation, of wavelengths less than and including 313 millimicrons, evaluated according to the spectral erythemic response curve, should not be less than the erythemogenic equivalent of 20 microwatts (200 ergs per second) per square centimeter of homogeneous radiation of the wavelength, of maximum erythemogenic effectiveness, which wavelength, for practical purposes, is taken at the emission line of mercury vapor, at 297 millimicrons (more exactly, 2,967 angstroms).

Using homogeneous radiation of wavelength 297 millimicrons, it may perhaps be possible to cure rickets by exposure to intensities that are lower than 20 microwatts per square centimeter, provided the treatment is sufficiently prolonged. However, such a source is not in common use and, hence, need not be considered.

Although there appears to be no close relationship between the spectral erythemic response and the spectral activation curve of ergosterol in the production of Vitamin D and in the healing of rickets, the erythemal reaction is taken as a criterion for judging the effectiveness of the lamp, for three reasons: (*a*) It is practically the only physiologic reaction that is established with a relatively high degree of accuracy;[2] (*b*) in the case of exposure to intense sources of ultraviolet radiation, it is a simple and practical means of preventing severe burns, and (*c*) in the case of weak sources of ultraviolet radiation, it is an efficient safeguard against possible fraudulent sale of lamps that are deficient in ultraviolet radiation.

Furthermore, the preliminary erythema test will no doubt always be made on new subjects, even after the lamp has been standardized by some form of dosage intensity meter. Hence, it seems natural to use the erythemal instead of the antirachitic or a photochemical action (the production of vitamin D) as a basis of standardization.

It is to be noted that the specification of a minimum of 20 microwatts per square centimeter is an erythemogenic dosage intensity that appears to meet the average conditions as known today; serving, as already stated, as a guide in avoiding burns from overexposure to intense sources of ultraviolet radiation, and eliminating possible fraud in the sale of lamps that do not emit ultraviolet radiation in sufficient intensity to qualify as efficient therapeutic agents. As mentioned in the preceding paper, the ultraviolet radiant flux emitted by the present day "professional models" of the various kinds of therapeutic lamps greatly exceed this specified minimum value.

It is hardly to be expected that this specification will meet all emergencies without supplemental information. For example, suppose that a lamp should be developed, consisting of a high voltage (with condenser) discharge between two electrodes of magnesium, in which most of the ultraviolet radiation is emitted in a single, intense line at about 280 millimicrons. Such a source is well known to physicists.

The emission line of magnesium at 280 millimicrons is in the region of a strong absorption band in ergosterol, which substance has a powerful antirachitic action after exposure to ultraviolet radiation. No data are at hand showing what photochemical action this single emission line would have on the human skin; but it is interesting to note that, because of the low susceptibility of the skin in this spectral region, the erythemal reaction[2] would be relatively weak. On this basis it would therefore appear to be possible to apply a more powerful irradiation from such a lamp without producing a burn than with lamps now in use. Whether such a procedure is desirable is undetermined, though it might be useful in researches on inanimate material. Such sources are now available in the form of cored carbon arcs, which, however, are not so nearly homogeneous in ultraviolet radiation.

A recently introduced source of ultraviolet radiation that requires further physiologic tests is the so-called cold quartz lamp, in which about 95 per cent of the total radiation of wavelengths less than and including 313 millimicrons is emitted in the resonance line of mercury at 254 millimicrons (more exactly, 2,537 angstroms[3]).

The ultraviolet radiant flux,[3] as well as the erythemogenic efficiency of such a lamp is relatively high. Nevertheless, in spite of its high erythemogenic efficiency, further biologic information is needed concerning its effectiveness in healing rickets and in the activation of ergosterol; for, according to published records,[4] when the source of ultraviolet consists of wavelengths longer than 2,750 angstroms, over 60 per cent of ergosterol is converted into vitamin D, whereas, if the lines at 2,537 and 2,654 angstroms are present, only a small amount of ergosterol is converted into vitamin D, after which a further exposure gradually destroys the vitamin D that was formed on first exposure.

As stated in a previous paper,[3] since the publication[4] of experiments on irradiation of cod liver oil, ergosterol and cholesterol, showing that wavelengths shorter than 280 millimicrons are destructive to vitamin D, the feeling is abroad that it is undesirable to use ultraviolet rays of wavelengths shorter than about 280 millimicrons for therapeutic purposes, especially in lamps sold for home use.

THE ERYTHEMOGENIC UNIT OF DOSAGE

The ultraviolet unit of dosage cannot be a concise, tangible specification like a quinine pill. Rather, in a broad sense, the aforementioned specification of 20 microwatts per square centimeter of homogeneous radiation, of the wavelength 297 millimicrons, is analogous to a 1 grain (0.065 Gm.) pill of pure quinine sulphate; and the equivalents of heterogeneous ultraviolet radiation, from various sources, are vaguely analogous to the equivalents that would be specified if, instead of pure quinine sulphate, the material were administered in the form of cinchona bark, or quinine derivatives, of various degrees of purity or concentration.

This analogy is not complete, but it should convey the idea of the difficulties encountered in attempting to standardize ultraviolet dosimetry. For example, the physiologic effect of the pure quinine may perhaps be different from that of cinchona bark. Similarly, the physiologic effect of the homogeneous emission line (297 millimicrons) may be somewhat different from that of the heterogeneous source of ultraviolet radiation. Indeed, differences in the color of the erythema and in the amount of pigmentation produced by different sources are recognized.

However, some sort of standardization is needed in order that workers can compare their results. At present, only in a very general way are experimental results comparable. For example, one worker uses a cadmium photocell standard; others use foot candle, or fluorescent photometer standards; and still others use the mercury lamp as a "high sun standard," with no certainty of constancy of the source.

The unit of dosage of ultraviolet radiation has been discussed by various writers, including myself.[5] The various proponents have dealt with this question from two points of view; viz., the specification of the unit in terms (*a*) of radiant power in microwatts per square centimeter, and (*b*) of total energy in ergs per square centimeter. In my previous paper,[1] the ultraviolet unit of dosage was defined in terms of radiant power and, as used, was merely a symbol or an abbreviation to summarize a complex of several variables that enter into the administration of ultraviolet radiation.

In the present communication the unit of dosage is specified in terms of the total ultraviolet energy utilized. When followed through to its logical conclusion, the utilization of the total radiant energy, homogeneous radiation of wavelength 297 millimicrons being employed as a standard, appears to be the simplest, the most direct and the most easily reproducible procedure yet tried experimentally.

This specification is based on the results of an extensive investigation[6] in which a comparison was made of the erythema produced by measured amounts of heterogeneous ultraviolet radiation, evaluated by a balanced thermocouple and filter radiometer. In this evaluation, the erythema produced by a measured amount of homogeneous radiation of wavelength 297 millimicrons was used as a standard. In spite of the fact that the sources differed very markedly in ultraviolet spectral energy distribution, a close agreement was obtained between the observed and the calculated exposures, indicating that the radiometric evaluation is reliable. Since such a radiometer is nonselective and can be calibrated in absolute units, it appears to be the most reliable primary standard of comparison we have yet tested.[6]

The following specification, using total energy, instead of radiant power, is merely an amplification of my earlier suggestions[5] of using erythemogenic equivalents, which could not be specific at that time because of the lack of rigidly controlled physical and physiologic (erythemal) measurements, now available.[6] The present specification appears to meet all the requirements that can be foreseen at present. If it does not greatly simplify the manner of recording the experimental data, it will at least introduce a reproducible system that will bring some order out of the present chaos.

In my previous paper[1] (numerical data revised, herewith) it was shown that, for the various sources of heterogeneous ultraviolet radiation of wavelengths less than and including 3,130 angstroms, the erythemogenic equivalent of 20 microwatts per square centimeter of homogeneous radiation of wavelength 2,967 angstroms, in microwatts per square centimeter, is approximately as follows: the sun at midday, midsummer, midlatitude, sea level (20 ÷ 0.22 =) 91; the Mazda S-1 lamp, 80; the Mazda S-2 lamp, 93; the high temperature quartz mercury arc, 58; the so-called cold quartz mercury vapor lamp, 36; the carbon arc, 45 to 90 (the latter value is estimated; depending on the electric current, the kind of carbons, and windows), and the Mazda CX tungsten filament lamp 130 (estimated).

Furthermore, in the preceding paper[1] it was shown that it requires about 200,000 ergs per square centimeter of homogeneous radiation, of the wavelength of maximum erythemogenic effectiveness, to produce a minimum perceptible erythema on the average untanned skin. The unit of dosage should therefore be some lower value in order to guard against overexposure.

If we adopt 10,000 ergs (10 kiloergs) per square centimeter of homogeneous radiation of the wavelength 297 millimicrons as the erythemogenic unit of dosage of ultraviolet radiation and call it the Finsen unit (F. U.), then the erythemogenic equivalent dosage of heterogeneous ultraviolet radiation, of wavelengths less than and including 313 millimicrons, emitted by the various aforementioned sources is as follows:

1 F. U. = 10,000 ergs per square centimeter of standard wavelength, 297 millimicron, radiation.
= 45,500 ergs per square centimeter of midday, midlatitude, midsummer, sea level, solar radiation.
= 40,000 ergs per square centimeter of Mazda S-1 lamp radiation.
= 46,500 ergs per square centimeter of Mazda S-2 lamp radiation.
= 29,000 ergs per square centimeter of quartz mercury arc radiation.
= 18,000 ergs per square centimeter of "cold quartz" radiation.
= 22,500 to 45,000 ergs per square centimeter of carbon arc radiation. (The latter value is estimated, depending on the kind of carbon and on the window.)

From the foregoing correlation of the physiologic and the radiometric measurements it will be evident why much of the published data, now available, appears to be inconsistent and may be misleading. The published measurements do not include a factor that equates the erythemal response. For example, some time ago I was called on to explain why the short wavelength ultraviolet solar radiation, which was relatively large in amount as measured with a photoelectric cell, did not produce an erythema in a much shorter time than a much smaller amount of ultraviolet radiation emitted by a quartz mercury arc lamp. If the experimenter had multiplied the total ultraviolet radiation measurements by the erythemogenic efficiencies of these two sources (not available then; also by a factor for selectivity of his photocell), he would have found a closer agreement in their erythemal effects.

[6] Coblentz, W. W.; Stair, R., and Hogue, J. M.: Tests of a Balanced Thermocouple and Filter Radiometer as a Standard Ultraviolet Dosage Intensity Meter, Bur. Stds. J. Research **8**: 759 (June) 1932. (R. P. No. 450, 10 cents; obtainable only from the Superintendent of Documents, Washington, D. C.)

For, as mentioned in a recently published paper,[6] when the factor that equates the physiologic (erythemal) response is taken into consideration there is good agreement between the calculated and the observed times of exposure to produce a minimum perceptible erythema, employing sources differing widely in spectral quality and in total intensity of ultraviolet radiation useful for therapeutic purposes.

CONCLUSION

As an illustration of the practical application of the Finsen unit, let us suppose that, from practical experience, it is found that the average person can be given 20 Finsen units daily of Mazda S-2 irradiation without producing an overexposure, and that the particular Mazda S-2 lamp available for use emits a radiant flux of 100 microwatts per square centimeter (1,000 ergs per second) at the standard operating distance. Then, from the described correlations, it follows that 20 Finsen units (46,500 × 20) = 930,000 ergs per square centimeter of Mazda S-2 lamp radiation and hence that an exposure of (930,000 ÷ 1,000 =) 930 seconds, or 15½ minutes daily, is required to produce a minimum perceptible erythema.

If it requires 100 exposures to effect a cure, this will amount to a total of 2,000 Finsen units of Mazda S-2 lamp radiation. This seems simpler than to report the total energy in ergs, which in this instance would amount to 93,000,000 ergs per square centimeter of Mazda S-2 lamp radiation.

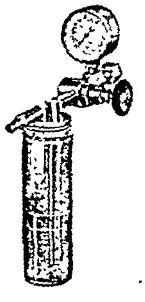
GUEDEL OXYGEN METER ACCEPTABLE

The Guedel Oxygen Meter, manufactured by the Foregger Company, Inc., New York City, is designed to indicate visibly the volume of oxygen flowing into a therapeutic oxygen tent. According to the firm, the Guedel Oxygen Meter consists of a control valve to reduce and regulate the pressure of the oxygen from a supply cylinder and a sight-feed to indicate the amount of oxygen fed to a patient within a tent or therapeutic gas chamber. A control valve is provided with a standard pressure gage designed to indicate the pressure in the oxygen tank. The sight-feed is essentially a wash bottle containing a metal gas tube with five holes submerged below the water level. Each hole is calibrated, according to the firm, to permit the passage of 2 liters of oxygen per minute, making a total of 10 liters per minute maximum. The firm claims that this meter is reliable and that the exact amount of oxygen flowing may be read within an error of considerably less than 2 liters per minute within the range of 10 liters per minute.



Guedel Oxygen Meter.

The Council on Physical Therapy declares the Guedel Oxygen Meter acceptable for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

COMPARATIVE STUDIES OF MERCUROCHROME-220 SOLUBLE AND OTHER ANTISEPTICS

The Council has authorized publication of the appended report, "Comparative Studies on Mercurochrome and Other Antiseptics," by W. F. von Oettingen, O. V. Calhoun, V. A. Badertscher and R. E. Pickett. In authorizing publication of this report the Council directed that it be explained that Hynson, Westcott & Dunning have agreed to revise their advertising claims in accordance with the findings of the paper. The Council voted to continue the acceptance of Mercurochrome-220 Soluble, and the description of the product appears in New and Nonofficial Remedies, 1932.

W. A. PUCKNER, Secretary.

COMPARATIVE STUDIES ON MERCUROCHROME AND OTHER ANTISEPTICS

W. F. VON OETTINGEN, M.D., PH.D.
WITH THE ASSISTANCE OF
O. V. CALHOUN, B.S.
V. A. BADERTSCHER, B.S.
AND
R. E. PICKETT, B.S.
CLEVELAND

The manufacturers of mercurochrome-220 soluble[1] (Hynson, Westcott & Dunning), in their advertisements, made claims which seemed inherently questionable; namely, the deep penetration of the drug and at the same time persistent stain of the surface of the skin. The latter would indicate local fixation rather than deep and ready penetration. On the other hand, they claimed a persistent local antiseptic action, attributed to the local fixation. It appeared puzzling that a dye should be at the same time so firmly fixed, and, therefore, essentially insoluble and nevertheless should have marked antiseptic properties; i. e., be capable of reaction with infective agents. The attention of the manufacturers was called to this apparent contradiction by the Council on Pharmacy and Chemistry. They replied at some length, submitting arguments, and citing data from published and unpublished investigations. The arguments did not appear convincing. The references were consulted in the original text; but in some of these the data were scanty, some of the methods used were uncritical, and some of the results were so dubious, that they were unconvincing. It appeared, therefore, that these claims would require stronger evidence to be tenable, and the subject seemed to be sufficiently important to justify the Council in undertaking an independent investigation. This was assigned to the Department of Pharmacology of the School of Medicine of Western Reserve University, under the direction of Torald Sollmann and W. F. von Oettingen. It was decided to confine the investigation essentially to the claims in question, namely, bacteriostatic action and penetration, but to broaden the conclusions by comparison with other

From the Department of Pharmacology of Western Reserve University School of Medicine.

This investigation has been made with the assistance of a grant from the Committee on Therapeutic Research, Council on Pharmacy and Chemistry, American Medical Association.

[1] For the sake of brevity, this product is hereafter referred to as "mercurochrome."

antiseptics. The methods were selected to give definite answers pertinent to the questions; but refinements beyond this were avoided, since they would tend to narrow the scope of the inquiry.

ANTISEPTIC EFFICIENCY

Since the culture-efficiency is not directly at issue, it appeared sufficient to cite the relevant data from the literature. It may not be amiss to point out certain sources of error that may be concerned in the discordant results, and especially in transferring conclusions to other conditions, without adequate controls:

1. In testing the antiseptic action of drugs by applying these to the skin or to the mucous membranes, and sponging the treated area with sterile gauze swabs, and streaking these on sterile culture mediums, enough antiseptic may be transferred to produce bacteriostatic action. The absence of the transfer of effective quantities of the drug should be confirmed by inoculating the cultures with fresh test organisms. The self-defense mechanism of the host may also develop sufficient antiseptic action, as recently pointed out by Arnold and his co-workers,[2] so that treated and untreated areas must be compared. Norton and Novy[2] failed to demonstrate this effect. Presumably it varies in degree and importance.

2. Certain physicochemical conditions must be observed in testing the antiseptic properties. The work of Michaelis and Dernby[3] on hydrocupreines, of Laqueur, Sluyters and Wolff[4] on acridine dyes, of Hiller and Stamler,[5] of Davis,[6] and of Todd[7] on mercurochrome itself, indicates that the antiseptic action may vary considerably with the p_H of the solutions. The presence of serum and proteins also may affect the antiseptic efficiency either favorably or unfavorably, as pointed out by Browning and his co-workers,[8] and by Morgenroth and his school.[9] The solubility of the drug under different conditions, especially with different p_H, is also important (Michaelis and Dernby); so also is its colloidal or crystalloidal state. For many antiseptics, it was found that the number of organisms in contact with the antiseptic, the presence of blood and pus cells and of organs influence markedly the efficiency (Laqueur,[4] Langer,[10] Wells[11]).

Great caution is therefore necessary in transferring results obtained in test-tube experiments; and even animal experiments may give misleading results, for instance, on account of different structure of the tissue, as pointed out by Laqueur[12] for the white mouse in relation to the experiments of Morgenroth with ethyl hydrocupreine (optochin). Morgenroth, Browning and others have emphasized, therefore, that culture experiments afford only general information which must be controlled by the animal experiment, and finally by very critical observations of an adequate number of clinical cases.

The experimental work done on the antiseptic action of mercurochrome may be grouped as studies on the antiseptic action in cultures, on the local antiseptic action in vivo, and on the antiseptic action in vivo with systemic administration. Only the first two groups are of interest for this report.

ANTISEPTIC ACTION OF MERCUROCHROME ON BACTERIAL CULTURES

General Antiseptic Efficiency in Cultures.—From the data collected from the literature it appears that with short exposure (from one to five minutes), concentrations of from 1:100 to 1:5,000 are necessary to kill bacteria; with longer exposure of from fifteen to sixty minutes, concentrations of from 1:5,000 to 1:10,000 are required, and with exposure for from twenty-four to forty-eight hours concentrations of 1:20,000 to 1:40,000 were found to be antiseptic. It also appears that the antiseptic efficiency is increased by an acid reaction. According to Birkhaug,[13] the bactericidal efficiency of mercurochrome is less than that of hexyl resorcinol, mercuric chloride and iodine, but higher than that of phenol. It appears, in this connection, that in wounds and mucous membranes the bactericidal action, the destruction of bacteria, is of greater importance than the bacteriostatic action, the inhibition of bacterial growth, unless the tissue is continuously bathed with the antiseptic in a soluble and active form.

The Effect of p_H on the Antiseptic Action of Mercurochrome.—Young, White and Swartz[14] observed no growth of Staphylococcus aureus in mercurochrome urine mixtures of the p_H 6.4 in concentrations of 1:1,000 after one minute, and of 1:5,000 after five minutes' exposure. Lancaster, Burnett and Gaus[15] saw no growth of the organisms in mercurochrome Ringer solutions of higher p_H in concentrations of 1:1,000, after six to ten minutes, and in such of 1:10,000 after thirty to sixty minutes' exposure; mercurochrome being, therefore, less effective at a higher p_H. Todd[7] similarly found the antiseptic action of mercurochrome for several organisms considerably reduced, near the neutral point, as compared with the more acid solutions. This was confirmed by Hiller and Stamler,[5] who inoculated broth of different p_H (7.5 to 5.3) containing varying concentrations of mercurochrome with B. coli cultures. After forty-eight hours' incubation, one loop of each tube was transferred to endo agar plates, which were read after incubation for twenty-four hours. Under these circumstances, they found that concentrations of 1:5,000 killed the organisms at every p_H. With concentrations of 1:20,000, there were a few colonies at p_H 7.5 to 7.1, and with lower p_H the cultures were negative. Concentrations of 1:40,000 showed luxurious growth in alkaline mediums and no growth in the acid series, except for a peculiar range between p_H 6.3 and 5.9.

Effect of Mercurochrome on Different Organisms.—Birkhaug[13] determined the phenol coefficient of mercurochrome for different organisms as follows: Staphylococcus aureus, 1.7; Streptococcus hemolyticus, 3.0; B. coli, 2.0; gonococcus, 2.2; B. anthracis, 4.6; B. subtilis, 3.7. Simmons[16] found that 2 per cent aqueous solution of mercurochrome failed to kill Staphylococcus aureus in ten minutes or Streptococcus scarlatinae in five minutes; but it killed Streptococcus pyogenes in two and one-half and Escherichia coli in one minute. The favorable results reported by Scott and Hill[17] appear to have been due chiefly to the solvent, judging by the data of their table. According to Simmons, all the mercurochrome solutions failed to kill the spores of B. anthracis in three hours, being in this respect distinctly inferior to tincture of iodine, which killed spores after one hour's contact. However, even this time is probably far too long to have any real therapeutic importance.

Eyre, Notton and Pope[18] determined the minimal inhibiting concentration of mercurochrome as 1:3,500 for B. coli and as 1:8,000 for Staphylococcus longus-hemolyticus. Swartz and Davis[19] found for gonococci as minimal antiseptic concentration after five minutes 1:4,000, and after twenty minutes' contact 1:16,000. It is not possible to explain why these results are so different from those reported by Birkhaug, who found 1:180 as the highest dilution of mercurochrome that would kill gonococci after ten but not after five minutes.

It appears, therefore, that the bactericidal efficiency of mercurochrome, as of most antiseptics, varies with different organisms.

Effect of Serum and of Blood on the Bactericidal Action of Mercurochrome.—In the presence of 50 per cent serum, Miss Hill[20] found the effective concentration of mercurochrome with one minute's exposure to be for B. coli 1:200, for Staphylococcus aureus 1:90, for B. pyocyaneus 1:90, and for pneumococci 1:50. Lancaster, Burnett and Gaus[15] found the minimal effective concentration in serum as 1:100 in one hour, and as 5:100 in ten minutes in contrast to 1:1,000 in from six to ten minutes, and of 1:10,000 in from thirty to sixty minutes in Ringer solution. In comparing the efficiency in dilutions made with 50 per cent human serum and with distilled water, Birkhaug[13] found the highest effective dilution killing organisms after ten but not after five minutes for Staphylococcus aureus 1:40 and 1:140; for Staphylococcus hemolyticus 1:70 and 1:300; for B. coli 1:30 and 1:60; for gonococci 1:50 and 1:80, and for B. anthracis 1:60 and 1:320. The first of each pair of numbers refers to serum, the second to water dilutions. Hill and Ellis[21] reported experiments on the protection of animals against multiple lethal doses of pneumococci by giving mercurochrome, horse serum alone, and mixtures of mercurochrome and horse serum. The animals treated with the mixture showed a markedly favorable therapeutic response as compared with mice receiving either mercurochrome or horse serum alone. The authors themselves stated that this therapeutic action is not related to direct germicidal action, and it appears to be a nonspecific reaction.

From these data it appears that the presence of serum does greatly reduce the antiseptic action of mercurochrome.

Young, White and Swartz[14] compared the antiseptic action of mercurochrome in urine (p_H 6.4) with that in hydrocele fluid. They found that in the urine mixture B. coli and Staphylococcus aureus were killed by concentrations of 1:1,000 in five minutes, and in the hydrocele fluid only after sixty minutes' contact. In defibrinated blood, Piper[22] found that mercurochrome inhibited the growth of Staphylococcus hemolyticus completely in concentrations of 1:8,000 in forty minutes, and with 1:6,000 only two colonies were counted at the end of one hour. Since the number of experiments was apparently limited and no details of the technic were given, they need further confirmation. Simmons[16] found that mercurochrome in aqueous solution of 1:100 killed staphylococci in fifteen minutes, but not when blood was added to the mixtures. J. E. Walker[23] found that mercurochrome in concentrations of from 1:25,600 to 1:400 has no appreciable effect on the bactericidal action of fresh defibrinated blood for B. coli, 1:100 sterilized the blood for staphylococci and 1:200 for streptococci. Brill and Myers[24] found that mercurochrome in blood culture mediums had no antiseptic value, even after twenty-four hours' contact in concentrations of 1:10,000, as tested with Streptococcus viridans, Staphylococcus albus and B. coli.

Hench, Snell and Greene[25] state that, in bile, mercurochrome is bactericidal in a concentration of 1:20,000. Hill and Scott,[26] using the Beckwith method, found that mercurochrome bile mixtures of 1:1,000 killed all bacteria tested except Staphylococcus aureus, within one hour, in the same time concentrations of 1:50,000 killed B. typhosus 3, the experiments being controlled with pure bile. Comparison of these figures with those obtained by Young and his co-workers indicates that the presence of bile has a distinct inhibiting action on the antiseptic action of mercurochrome. This was confirmed by Simmons,[16] who found that aqueous mercurochrome solutions of 1:5,000 killed typhoid bacilli in five minutes, whereas, with the same concentration in ox bile, thirty minutes' contact was necessary to kill the organisms.

THE LOCAL BACTERIOSTATIC ACTION OF MERCUROCHROME

The local bacteriostatic action of mercurochrome has been studied in several ways. Tinker and Sutton[27] reported that a 5 per cent solution of mercurochrome in 50 per cent alcohol failed to kill most of the resistant and some of the less resistant pathogenic bacteria when applied to the skin. Scott and Hill[17] pointed out that, although aqueous solutions of 1 to 10 per cent are bactericidal against certain organisms in vitro, such solutions are generally less effective in disinfecting the skin. Later they[28] found that a 2 per cent acetone-alcohol-aqueous solution gave better results. This was confirmed by Simmons,[16] who reported that 5 per cent alcoholic (50 per cent) solutions gave somewhat better results than the aqueous solutions but was less effective than alcoholic solutions of iodine (3.5 per cent) in killing certain spore forming bacteria. This was substantiated by Reddish (quoted from Simmons). However, none of the agents are absolutely effective, and there may be some doubt as to the significance of these differences. Simmons found in disinfection experiments with normal rabbit skin that mercurochrome had less bactericidal action on Staphylococcus aureus, Streptococcus pyogenes, Streptococcus scarlatinae, B. coli and Claustridium welchii than had iodine solution. A 2 per cent mercurochrome solution failed to kill the organism either on or in the skin in fifty-five out of fifty-six experiments; 2 per cent acetone-alcohol-aqueous solution caused some reduction of the organisms but failed to disinfect the skin in forty-five out of fifty experiments. The 5 per cent alcoholic (50 per cent) solution reduced the number of bacteria in a similar way but failed to disinfect in forty-five out of forty-six experiments. The 2 per cent acetone-alcohol-aqueous solution failed to kill or to lower the virulence of B. anthracis spores, whereas tincture of iodine was effective. Reddish and Drake[29] reported similar studies, which led them to believe that as a skin disinfectant the 2 per cent acetone-alcohol-aqueous solution of mercurochrome is as effective as iodine, the 2 per cent aqueous solution being less effective. Bloomfield[30] painted areas of the tongue with 10 per cent aqueous solutions of mercurochrome. Swabs taken ten minutes later and cultures showed a profuse growth of green streptococci. Rodriguez[31] studied the antiseptic action of mercurochrome on the mucous membranes of the mouth. He found that rinsing of the mouth with 2 per cent mercurochrome solution had no effect in ten out of ten cases after one minute contact; after three and five minutes' exposure there was a decided reduction in the number of colonies. The germicidal effect was most marked against gram-negative cocci, less against gram-positive bacilli, and practically nil against gram-positive cocci. The 5 per cent alcoholic solution gave better results; but in only two out of ten cases was the disinfection complete.

Mayes and Ullian[32] recently reported experiments on the antiseptic action of mercurochrome in the birth canal. They report that after lavage with 2 per cent aqueous mercurochrome solution, the number of colonies was considerably reduced as compared with untreated cases and with lavage with compound solution of cresol. In a more recent publication, Mayes[33] used mercurochrome in the preparation of the birth canal by spraying a 4 per cent aqueous solution on the perineum and injecting 3 drachms (11 cc.) of a 2 per cent solution into the vagina. He compared the morbidity of patients treated in this way with that of patients treated only externally with iodine. He reports that the percentage of morbidity of the latter group was 12.4 per cent (2,072 cases) as compared with 5.6 per cent in the first group (5,102 cases). From this the conclusion appears justified that the prepartum disinfection of the birth canal with mercurochrome does decrease the incidence of infective responses. However, Mayes has apparently not made comparative observations with other antiseptics applied in the same manner as mercurochrome. An editorial comment[33a] in The Journal states that "other obstetricians, among them Williams at Johns Hopkins and Baldwin at the University of Michigan, failed to obtain any striking results" but that Henderson of Colorado reports a similar reduction of the morbidity. "Although the numbers of this study from the University of Colorado are not large, the care with which the experiment has been controlled gives significance to the result."

The local antiseptic action of mercurochrome on abscesses has been studied by Sanner and Hill.[34] They produced artificially abscesses in guinea-pigs and treated these with 1 and 2 per cent solutions of mercurochrome. They observed a reduction of the number of organisms and a more prompt healing than in the controls. However, their experiments do not seem conclusive, because the controls were not treated in the same way with some inert material, such as physiologic solution of sodium chloride, to eliminate the possibility of having removed the germ mechanically by lavage.

This survey of the literature does not pretend to be exhaustive; but it includes all the original investigations that were cited by the manufacturers in support of their claims for mercurochrome.

Because these data do not give definite evidence of the bacteriostatic action of mercurochrome, additional experiments were carried out in this laboratory:

The skin of patients preparing for an operation was painted with the antiseptic solutions twelve hours, then one hour, and again fifteen minutes prior to the operation, three coats being applied at each treatment and each coat being allowed to dry before the next was applied. The solutions used were 3 per cent alcoholic solution of iodine, an alcoholic solution of mercuric chloride 1:4,000, and 2 per cent acetone-alcohol-aqueous solutions of mercurochrome, gentian violet and hexylresorcinol. The solvent for these dyes consisted of 10 parts of acetone, 52.5 parts of alcohol and 37.5 parts of water, as suggested by Tinker and Sutton.[35]

In this way nine coats were applied to the skin of patients, and no further treatment was given prior to the operation. At this time a specimen of skin was excised, which was delivered the same day with aseptic precautions, and strips of 0.5 by 1 cm. surface were implanted into agar plate cultures of Staphylococcus albus before they were congealed and incubated for twenty-four hours at 37 C. None of five samples treated with mercurochrome, coming from different patients, showed a bacteriostatic halo around the tissue in the culture, thus indicating that the dye was fixed on the surface of the skin and did not develop any bacteriostatic action in contact with the culture. Similarly negative results were also obtained with one sample taken one hour after the administration of three coats. Of the other antiseptics used in these experiments, mercuric chloride and iodine showed marked bacteriostatic action in two out of two cases; gentian violet exhibited in two out of two cases a distinct, and hexylresorcinol in three out of three no bacteriostatic, property.

These experiments with human skin had to be discontinued, because stitch abscesses occurred even after nine coats of the mercurochrome, applied in intervals as described. This is a practical confirmation that mercurochrome has no or only very little bacteriostatic value, whereas mercuric chloride, iodine and, to a less degree, gentian violet show bacteriostatic properties. The manufacturers of mercurochrome claim that the acetone-alcohol-aqueous solution of mercurochrome is more effective on the skin than is the aqueous solution, because it penetrates fat. As has been pointed out, samples of skin painted with nine coats of the alcohol-acetone mercurochrome did not arrest bacterial growth. This does not exclude the possibility that the moist solution may kill some bacteria on the surface, partly by the dye and partly by the solvent itself. Further experiments with mercurochrome were made on the shaved skin of rabbits, to which one coat of 2 per cent aqueous solution of mercurochrome was applied so as to obviate the complication of the disinfectant action of the alcohol-acetone solvent. From this skin one sample was removed immediately after the drying, another after one hour, and a third after four hours; none of these showed a bacteriostatic action when tested as described.

THE PENETRATION OF MERCUROCHROME

Deep penetration of mercurochrome is one of the main claims of the manufacturers. Young, White and Swartz [14] stated that, during intravenous injection into the rabbit ear, the dye spread within a few seconds from the vein into the tissues, so that the whole ear assumed a reddish pink color, which persisted with varying intensity for from twenty-four to forty-eight hours. In order to determine the penetration of mercurochrome into the tissue of the urinary tract, they injected an ounce of a 1 per cent solution into the urinary bladder of a rabbit by means of a catheter. Examination of frozen sections and of paraffin sections of the formaldehyde hardened tissue showed a deep staining of the epithelial layer of the urethra; this was most marked in the superficial layer, less distinct in the mucosa, and in some places even the muscularis was stained. Similar experiments on the staining of the renal pelvis were performed by O'Conor [36] in dogs. He opened the bladder in the median line and injected the solutions of different antiseptics into the pelvis by means of a ureteral catheter. He found that mercurochrome stained the superficial layers and that it was uniformly distributed throughout the submucosa and the muscularis. Examination of serial sections of the kidney twenty minutes after the injection of mercurochrome by gravity reveals that the dye had penetrated the tubules up to the glomeruli. Jones [37] studied the diffusion of 1 per cent solutions of mercurochrome and of other antiseptics into cervical mucus placed in petri dishes and found that the diffusion velocity was most marked with acid fuchsin, followed by mercurochrome, gentian violet, acriflavine hydrochloride, mild silver protein and strong silver protein, in the order given. He also filled solutions of the same strength into empty excised intestines of rabbits and rinsed these afterward with water. He found that acid fuchsin, mercurochrome and acriflavine hydrochloride left deep and permanent staining, which went to the depth of the epithelium. Solutions containing 5 per cent of the dye and 5 per cent of glycerin were injected in quantities of 5 cc. into the vagina of rabbits and allowed to remain there for fifteen minutes. The microscopic examination showed a deep staining of the vagina and of the cervix. From the examination of frozen sections it appeared that the staining was not uniform, decreasing gradually in the higher sections; but in those sections which were stained the dye had penetrated into the muscularis. Todd [7] filled the bladder of one rabbit with 5 per cent solutions of mercurochrome and kept it filled for one hour, when the bladder was emptied. After twenty-four hours, the animal was killed, and it was found that the bladder was deeply stained throughout, and that also the peritoneum surrounding the bladder and the pelvis of the kidney was deeply stained. Sections of the tissue were evidently not made. All other references submitted by the manufacturers as evidence for the penetrating action of mercurochrome contain only statements without experimental data for these claims.

From the foregoing data it appears that the penetrating action of mercurochrome into the tissue has been studied with some care only in the urinary tract, and that studies on the penetrating action into the skin and the muscular tissue are missing. Experiments made to supply these deficiencies also brought to light serious sources of error that inhered in the earlier work:

Penetration of Leather.—Before further experiments were done on the penetrating action into living tissue, a model experiment was performed with leather, which has considerable structural and chemical similarity to dead tissue. For this purpose, pieces 5 mm. thick were chosen, half of which were extracted with ether in order to remove the fat. Both samples were painted with three coats of mercurochrome, or with other agents, as indicated in table 1, each coat being allowed to dry before the next was applied.

Table 1.—*Penetration of Mercurochrome, Gentian Violet and Iodine into Leather*

Antiseptic	Ether Extracted Leather	Untreated Leather
2% aqueous mercurochrome	stained 0.25 mm. deep in regular line	stained 0.25 mm. deep in regular line
2% acetone-alcohol-aqueous mercurochrome	stained 0.25 mm. deep in irregular line	less penetration than in ether extracted sample
U. S. P. tincture of iodine	stained 0.25 to 0.5 mm.; deep penetration, deeper in center	0.5 to 1 mm. deep; stained fairly uniform
aqueous solution of gentian violet 1/500	no penetration	no penetration

This table shows that the depth of penetration is best with iodine; next ranges the acetone-alcohol-aqueous solution of mercurochrome, the aqueous solution of mercurochrome, and last that of gentian violet, the latter showing no penetration. These experiments give a picture of the penetration of these agents into a fibrous colloid system which is actually penetrable and stainable by mercurochrome and somewhat analogous to the physical structure of dead tissues.

Penetration into Living Human Skin.—All samples of human skin that had been treated with nine coats of mercurochrome in 2 per cent acetone-alcohol-aqueous solution, as described previously, were studied histologically. In order to avoid solution of the dye and secondary staining, frozen sections were made of the fresh tissue and examined without contact with any solvents as well as after embedding in glycerin. The latter, however, did not change or dissolve the dye when the slides were examined immediately. It was found that only the most superficial corneous layer was stained. In no instance was a deeper penetration into the skin observed.

The same results were obtained by painting the tongue of dogs with 2 per cent acetone-alcohol solutions and aqueous solutions of mercurochrome, and identical results were found microscopically in sections of rabbit skin.

Penetration into Muscular Tissue.—In order to ascertain whether the dye stains the muscular tissue more readily and deeper than the skin, freshly skinned frog legs were placed in 2 per cent solutions of mercurochrome in water and in the acetone-alcohol-water mixture, and pieces were taken at intervals and studied microscopically. After thirty minutes with the aqueous solution, the muscle showed some staining only on the surface, about 0.5 mm, deep, the depth of the color being more marked on the extreme surface. After one hour the staining zone was about 1 mm. deep, and after eighteen hours the dye had penetrated deeper into the tissue. The intensity of the staining was, however, not uniform, some fibers being deeply stained, others less, and some not at all. The same results were obtained with the acetone-alcohol-aqueous solution, with the only difference that on longer exposure the tissue showed signs of dehydration.

In order to decide the reason why in these experiments the muscle fibers were not stained uniformly, the following experiments were made:

A 1 per cent aqueous solution of mercurochrome was injected into the aorta of a frog until the skin of the leg showed a definite pink color. After the removal of the skin the muscle showed no coloration. The sciatic nerve of one leg was then stimulated with a faradic current. This leg turned more pink than the other one, presumably because the violent contractions caused rupture of some blood vessels. This was confirmed by the microscopic examination of sections in which the staining in the immediate surrounding of the vessels was deeper, gradually losing in intensity.

---

[36] O'Conor, V. J.: Lavage of Renal Pelvis, J. A. M. A. **77**: 1088 (Oct. 1) 1921.

[37] Jones, Ray: Northwest Med. **21**: 182 (June) 1922; Urol. Cutan. Rev. **27**: 692, 1923.

The effect of mercurochrome on living muscle was also studied with isolated muscle fibers. Teased preparations of the musculus rectus abdominis and of the musculus gracilis of frogs were used. These were observed under the microscope, their life being tested by stimulation with a faradic current by means of a very fine electrode. It was found that those fibers which did not contract were immediately stained on the addition of 2 per cent aqueous mercurochrome solution; the others, only after the response to electrical stimulation had disappeared.

Similar experiments were performed with living frogs. Small areas of skin and of skin with muscle were snipped out of the leg, and then the animal was immersed in 2 per cent aqueous solution of mercurochrome for one hour. After this period the animal was killed and skinned, and sections were made through the muscular tissue. In every instance only the most superficial muscular layer was stained.

In a second series, wounds were produced by cauterization with a hot iron, and the animals treated as before. In these experiments also only the most superficial layer of the muscle was stained; the scab in the necrotic area was deeply stained, but the normal tissue beneath the scab showed no staining.

Instillation of 2 per cent mercurochrome in aqueous and in acetone-alcohol-aqueous solution into wounds of rabbit ears, made by cutting with a scalpel, by snipping out pieces with scissors, and by punching holes with an awl, gave results identical with those in the frog; that is, the stain was confined entirely to the dead tissue.

From these experiments it appears that mercurochrome does not readily penetrate the living muscle, even when the muscle is perfused with the dye through the vessels. On the other hand, dead or necrotic muscular tissue is deeply stained by the dye. As living muscle is in general much more easily penetrated by reagents than is the skin, its failure to be stained by mercurochrome is a further support of the observation *that the dye does not penetrate into the living layers* of the skin.

Since ophthalmologists have reported marked penetration for mercurochrome, enucleated frog eyes were placed in 2 per cent aqueous and acetone-alcohol-aqueous solutions of mercurochrome for twelve hours. After this period it was found that with both solutions the aqueous humor was stained and with the aqueous solution the lens had also been stained uniformly; with the acetone-alcohol-aqueous solution, however, only the surface, the whole organ being hardened. From this it appears that mercurochrome penetrates the dead cornea of the frog. Experiments with living frogs which were immersed in 2, 5 and 10 per cent aqueous solutions of mercurochrome for periods of from 15 to 120 minutes showed that the dye had penetrated the cornea with the 2 per cent solution after two hours, with the 5 per cent solution after one hour, and with the 10 per cent solution after five minutes. From these data it appears that the living cornea also is permeable to mercurochrome in 2 per cent aqueous mercurochrome solutions when exposed for a sufficient length of time. This may be due to the nature of the cornea, which is more akin to the stratum corneum, to cartilage and to dead leather than to active tissue.

Spreading of the Dye in Subcutaneous Tissue.—In living rabbits, 0.1 cc. of 2 per cent aqueous and of 2 per cent acetone-alcohol-aqueous solutions of mercurochrome, and 0.1 cc. of U. S. P. tincture of iodine were injected into the subcutaneous tissue of the dorsal surface of the ear, between the skin and the cartilage, as far as possible from the main vessels. The diameter of the wheal was measured immediately and after one, two and twenty-four hours, with all three solutions. The immediate diameter of the wheal varied between 9 and 13 mm. and there was no material change within the first two hours. After twenty-four hours, a circumscribed stain could not be recognized but the larger part of the ear was definitely pink. When these ears were amputated under anesthesia and the skin stripped off from the cartilage, about 0.2 cc. of pink fluid was found between the two structures. The skin and the cartilage showed only a slight and superficial staining at the site of the injection, of the original size. Iodine could not be detected, which, however, may be due to the conversion into colorless iodide. Similar experiments performed with intracutaneous injections in rabbits also did not reveal any distinct spreading of the injected material. From these experiments it appears, therefore, that the dye either in aqueous or in acetone-alcohol-aqueous solution does not spread readily when injected into the tissue. The spreading of mercurochrome into the tissue with intravenous injection was studied with 2 per cent aqueous and 2 per cent acetone-alcohol-aqueous solutions. Injection of 0.5 cc. of aqueous solution into the ear vein of rabbits produced staining of the vessels and a slight dilatation of the capillaries and smaller vessels but no general staining or inflammation. Injection of 2 per cent aqueous mercurochrome solutions into the central artery of the rabbit ear caused a staining of the tissue surrounding the artery. This staining was not due to diffusion from the artery but was caused by mechanical spreading of the dye solution from the site of the insertion of the needle during and after the injection. As with hypodermic injections, there was some stained fluid between the cartilage and the skin, and the cartilage itself showed a sharply defined spot corresponding to the stained area of the skin; the sharpness of the outline indicates that the spreading was not due to gradual diffusion into the tissue.

From these experiments it appears that the dye does not readily diffuse from the vein, but when injected into the artery it is distributed over the capillaries and produces uniform staining of the whole ear.

Penetration of Mercurochrome into Mucous Membranes.—The penetration of the dye into the mucous membranes of the urinary tract was studied in five living rabbits. From 10 to 20 cc. of a 2 per cent aqueous solution of mercurochrome was injected slowly into the empty urinary bladder by means of a catheter and kept there for periods of from fifteen minutes to two hours. Then the bladder was emptied and removed from the living animal, under ether or barbital anesthesia. In these experiments, only the most superficial layer of the mucosa was found stained, and frequently the dye could be completely removed with a cotton swab. These results were confirmed by microscopic examination of frozen sections in glycerin. Two other rabbits were killed directly after the injection of the dye into the bladder, and fifteen minutes later the bladder was emptied, removed and studied. Two other animals were killed thirty minutes after the injection and the bladder was removed thirty and sixty minutes later. Under these conditions, that is, in the dead animals, there was a deep staining of the mucosa, submucosa, and also partly of the muscularis. There is therefore a pronounced difference, when the dye is left in the bladder of the dead animals. The penetration of the dye into the walls of the vagina was studied in two living rabbits by injecting 5 cc. of the 2 per cent aqueous mercurochrome solution into the vagina. When emptied and removed, after half an hour, from the living animal, under ether anesthesia, only the mucous and the most superficial layer of the mucosa was found stained. If, however, the animal was killed before the removal of the organ, the mucosa was deeply stained; ten minutes after death, and half an hour later, there was a deep staining of the mucosa, the submucosa and the muscularis.

The penetration of mercurochrome into the mucosa of the intestinal tract was studied in four rabbits and two cats. The animals received from 30 to 50 cc. of 2 per cent aqueous solution of mercurochrome by stomach tube. Loops of intestine were removed under ether anesthesia, one-half to one hour later, in case of the cats after from three to four hours, and examined macroscopically and microscopically. In all instances, only the mucous and the most superficial layer of the epithelium was stained. Similar results were obtained with frogs that were immersed in 2 per cent aqueous solutions of mercurochrome and allowed to swallow some of the solution. In two other rabbits, which were killed prior to the removal, the mucosa showed deep staining ten minutes after death, and after longer periods the muscularis also showed some staining. The dead rabbit intestine, on the other hand, as used in the diffusion experiments described below, showed a deep and uniform staining of all layers.

The penetration of mercurochrome through living frog skin was studied by immersing small living frogs in cylinders containing 2, 5 and 10 per cent aqueous solutions of mercurochrome. With the 2 per cent solution only a slight staining of the inside of the skin could be observed after one and two hours' exposure; with 5 per cent solutions this was more distinct after two hours; and with the 10 per cent solution the staining of the inside was already marked after immersion for fifteen minutes. As will be shown later, a 2 per cent aqueous solution of mercurochrome can hardly be considered as toxic; 5 and 10 per cent solutions, however, show distinct toxic reactions, and therefore the deeper penetration of the dye with longer exposure and more concentrated solutions cannot be considered as a phenomenon of the normal living skin. If mercurochrome penetrates so poorly in the normal frog skin, which is generally a good absorbing surface, it would penetrate less into the human skin, which is markedly less permeable than the frog skin.

From these experiments it appears that 2 per cent aqueous solutions of mercurochrome do not penetrate the living tissue of the urinary, genital and digestive tracts but that they stain dead or dying tissue deep and rapidly. This may explain the contradictory results of other workers. Besides, in making frozen or other sections, it is difficult to avoid the dissolving of the dye on the surface during this procedure, thus producing secondary staining of the dead tissue.

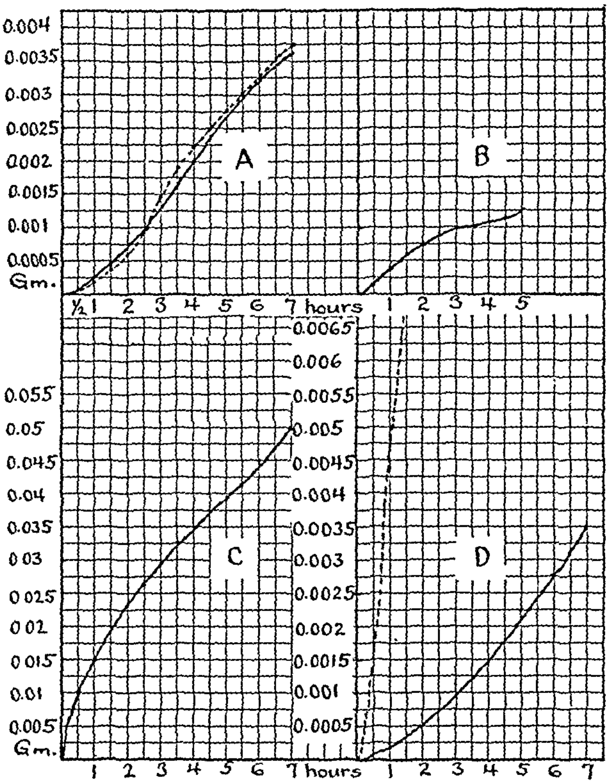
Diffusion of Mercurochrome Through Frog-Skin.—In order to obtain a conception of the rate of diffusion, in comparison with other drugs, the following experiments were performed:

The skin was stripped from the legs of frogs in the customary way, according to Sollmann,[38] attached to glass tubes of 0.75 cm. diameter, filled with 5 cc. of the solutions to be tested, and suspended in cylinders containing 150 cc. of Ringer solution (p_H 7.6). Care was taken that the level of the liquid inside and outside was the same, in order to avoid filtration pressure. The amount of the perfused dye was determined colorimetrically by adding enough of the original dye solution to 150 cc. of Ringer solution, in a cylinder of the same diameter, to match the color in the diffusion cylinder. In this way 2 per cent solutions of mercurochrome in aqueous and in acetone-alcohol-aqueous solution were compared with 2 per cent solutions of gentian violet in both solvents and with tincture of iodine and compound solution of iodine.

The accompanying chart illustrates these experiments. The rate of perfusion of both mercurochrome solutions is about the same (*A*). It is somewhat greater than with gentian violet (*B*), and considerably slower than with tincture of iodine (*C*), or compound solution of iodine. (It should be noticed that the iodine chart is based on a ten times larger unit.) It should also be mentioned that the rate of diffusion with mercurochrome is considerably slower when the diffusion is done in the opposite direction, namely, from the outside toward the inside, by using inversed sacs of skin. This has been observed by E. Wertheimer[39] for other dyes.

Diffusion experiments with compound solution of iodine and 2 per cent aqueous solutions of mercurochrome, short pieces of isolated rabbit intestine being used instead of frog skin, gave essentially similar results, as illustrated at *D*. It may also be noticed that with mercurochrome the diffusion is very slow in the beginning, and that it increases with the progressing deterioration of the skin. At lower temperatures the rate of diffusion remains exceedingly small for many hours. The great difference between the rate of diffusion between the two dyes and that of the solutions of iodine might be explained in part by the precipitant action of the latter on proteins, which would tend to alter the conditions of the membranes considerably.

Mercurochrome, gentian violet and iodine penetrate, therefore, the dead skin of the frog, and the dead rabbit intestine, although the absolute quantities are small, being with mercurochrome one five-hundredth after one hour and one fiftieth after four hours, of the total amount present in the inside of the membranes. For gentian violet, the corresponding values are one two hundred and fiftieth and one one-hundredth, and for iodine one twentieth for the tincture, and one fiftieth for compound solution of iodine, and one tenth and one fifth, respectively.



Diffusion through frog skin and rabbit intestine: *A*, frog skin: solid line, aqueous 2 per cent mercurochrome; broken line, acetone-alcoholic. *B*, frog skin: 2% gentian violet, aqueous. *C*, frog skin; U. S. P. tincture of iodine (scale reduced to one tenth). *D*, rabbit intestine; solid line, 2 per cent mercurochrome; broken line, compound solution of iodine, iodine 5 per cent, potassium iodide 10 per cent.

Toxicity of Mercurochrome for Living Tissue.—It has been claimed that the toxicity for living tissue is very low and that, according to Reddish, human spermatozoa survived the treatment with 2 per cent of mercurochrome in the ratio of one part of spermatic fluid and one part of mercurochrome solution for one-half hour; i. e., that they survived this period in a 1 per cent solution. These observations were made in a medium rich in proteins and it seemed, therefore, advisable to check this by other methods.

Effect of Mercurochrome on Ciliary Movements.—This was studied by observing the velocity of the ciliary movements of the ciliary cells of the frog pharynx after bringing them in contact with the solutions to be tested.

Two series of experiments were performed, one on small pieces of mucous membrane snipped from the pharynx and one on scrapings. The larger pieces represent more nearly the conditions under which the antiseptics are applied in practice; the scrapings show the effect on the isolated cells or on small masses. The clipped tissue, because of the smaller surface exposed and the lesser injury, is much more resistant than the teased preparation. Table 2 shows that 2 per cent mercurochrome, 2 per cent eosin, 2 per cent methylene blue (methylthionine chloride, U. S. P.) affect the clipped tissue only very slightly. Gentian violet in 2 per cent solution is distinctly more toxic, and this holds true to a higher degree for acriflavine hydrochloride, and especially for compound solution of iodine, of which solutions containing 0.125 per cent of iodine kill the cells immediately when brought in contact.

Acriflavine, sat. sol. less than 2%	..	..	..	15	all dead in 2 minutes
Compound solution of iodine, 0.125 per cent	..	..	..	Immed.	

* The figures indicate the time in minutes.

On account of the more rapid toxic effect, the teased tissue does not allow such a differentiation of the toxicity of the solutions used, but it reveals another phenomenon. Single cells were killed immediately, groups of cells after a few minutes and larger conglomerations only after a longer period of contact. Whereas the single cells were stained immediately, larger pieces were first stained on the edges and only considerably later in the center, although the dye had access to all parts of the tissue. From this it appears that only the injured or dead cells are stained and that the normal cells are not affected by the dye. This confirms the observations made with muscular and other tissues, in which only the necrotic or dead structures were stained. It was also noticed that the ciliary movements stopped as soon as the nuclei were stained, whereas diffuse staining of the protoplasma went parallel with the progressive slowing of the ciliary motility.

CONCLUSIONS

It appears that mercurochrome, when once fixed on the surface of the tissue, develops no bacteriostatic action in contact with bacterial cultures.

It penetrates only into the dead or dying mucous membranes of different organs, such as bladder, vagina and digestive tract, and it may diffuse through the cornea when in contact for a sufficient period.

It does not penetrate the living skin but is fixed in the most superficial layers of the epithelium, and it does not penetrate or stain normal muscular tissue.

It penetrates necrotic and dead tissue and stains them deeply and permanently.

The tissue toxicity of mercurochrome is relatively low, but the 5 per cent aqueous solution is distinctly injurious as judged by excised ciliated mucous membranes.

Mercurochrome cannot be relied upon to destroy bacteria that have penetrated into the living tissue of a wound or of the skin; it could do no more than disinfect the surface and the necrotic tissue. This limitation is shared more or less by all antiseptics so that no substance can be properly called a safe and certain wound antiseptic. No antiseptic takes the place of thorough cleansing and surgical treatment. When these are not practical, for "first aid" or for very superficial wounds, antiseptics are probably better than no treatment at all. The antiseptic efficiency of mercurochrome is not outstanding, and for skin disinfection the aqueous solution is distinctly inferior. The absence of irritation may be an advantage, especially with open wounds, and for prolonged treatment; but its limitations should always be borne in mind.

Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

THE INSTITUTE OF AMERICAN MEAT PACKERS GENERAL AND EDUCATIONAL ADVERTISING

Sponsors.—Institute of American Meat Packers, Chicago: an educational and research association of the meat packing industry established to further the welfare of the industry, to promote proper trade relations, to prosecute research on its products, and to promulgate advertising.

The following listed educational publications have been found acceptable as conforming to the Rules and Regulations with the exception of a few minor statements contained therein, which are being corrected in new revised editions. The institute agrees to maintain its future advertising and publications entirely correct and in compliance with the Committee's Rules and Regulations. The Institute of American Meat Packers is therefore entitled to display the seal of this committee on its publications and advertisements.

TITLES OF PUBLICATIONS

Institute of American Meat Packers—What It Is and What It Does.
The Purpose and Plan of the Institute of American Meat Packers.
Meat Cookery.
Pork Cookery.
Sausage.
The Perfect Pie Maker.
The Merits of Pure Lard.
Pure Lard.
Have a Heart.
Meat and the Well Balanced Diet.

The principal claims used by the association in promotion of meat follow:

1. Meat is an excellent source of high quality protein.

2. Lean meat, kidney, liver, heart and tongue are among the richest sources of food iron.
3. Lean meats are rich in phosphorus.
4. Lean meats supply most minerals required in nutrition in good quantity excepting calcium.
5. Lean meats are a good source of vitamin G (B_2).
6. The fat of beef animals is a good source of vitamin A, while oleo oil and oleomargarine made from it are rich in vitamin A and contain vitamin D.
7. While lean meats furnish modest quantities of calories, the fatter meats supply liberal amounts, and bacon and salt pork are among the richest food sources of calories.
8. Edible specialties, such as liver, kidney, heart and tongue, are good sources of vitamins A, B and G.
9. Meat is one of the most digestible of foods, its protein being almost entirely digestible.
10. The body fats of beef, pork and lamb, as well as prepared shortening such as lard or oleomargarine, are almost completely digestible (from 96 to 97 per cent).

RALSTON WHEAT CEREAL

Whole Wheat with Embryo added and only coarsest Bran removed

Manufacturer.—Ralston Purina Company, St. Louis.

Description.—Essentially whole wheat with coarsest bran removed and with added wheat embryo; contains more than twice as much embryo as whole wheat; in granular form.

Manufacture.—Dark hard winter wheat is cleaned by the usual screening, scouring, brushing and other milling operations, broken between steel reduction rolls, and passed over sieves of definite mesh to remove large bran flakes and fine flour; air currents effect the bran removal. Material of a definite granulation is selected for the product.

The wheat germ is passed over grinding rolls and appropriate screens to obtain a desired granulation, which is mixed with the prepared granular wheat. Before packing, the mixture is heated at 60 C. for about twenty minutes to destroy insect life. The final mixture is automatically packed in paper cartons.

Analysis (submitted by manufacturer).—

	per cent
Moisture	9.2
Ash	1.5
Fat (ether extract)	2.1
Protein (N × 5.7)	14.2
Crude fiber	1.2
Carbohydrates other than crude fiber (by difference)	71.8
Calcium (Ca)	0.04
Phosphorus (P)	0.37
Potassium (K)	0.35
Sodium (Na)	0.03
Magnesium (Mg)	0.27
Chlorine (Cl)	0.005
Iron (Fe)	0.006

Calorics.—3.6 per gram; 102 per ounce.

Vitamins.—The vitamin B, G and E content is more than twice that of whole wheat, owing to the addition of extra wheat germ. The product is considered a good to rich source of B and E, and a fair to good source of G.

Claims of Manufacturer.—A quick cooking wheat cereal containing more embryo and less bran than whole wheat; valuable for its vitamin B and food iron content.

STEERO BOUILLON CUBES

Manufacturer.—American Kitchen Products Company, New York.

Description.—A mixture of concentrated meat extract, concentrated vegetable extract, salt and beef fat, flavored with celery seed and pimento and an extract of fresh celery, parsley and leeks; in cube form.

Manufacture.—The vegetable extract is prepared by digesting vegetables in dilute hydrochloric acid until the protein is hydrolyzed and rendered soluble in water. The acid is neutralized with sodium carbonate, and the solution is filtered and concentrated in glass lined vacuum stills to a semisolid mass.

The meat extract is prepared by cooking fresh beef flesh in water.

The meat and vegetable extracts are mixed and heated, salt is added, and the mass is concentrated at about 100 C. to a dough-like consistency. Rendered beef fat which has been heated with celery, parsley and leeks is added to the hot dough-like mass and the heating is continued for a short time. After cooling, the mass is rolled and cut into cubes. The cubes are wrapped in wax-paper lined tinfoil by machinery and packed in tin boxes.

Analysis (submitted by manufacturer).—

	per cent
Moisture	6.8
Ash	68.2
Sodium chloride	62.5
Salt (NaCl) free ash	5.7
Fat (ether extract)	1.6
Nitrogen	3.5
Nitrogenous substances estimated as protein (N × 6.25) (only a portion of nitrogenous substances exist as protein)	21.9
Sucrose and reducing sugars	0.0
Creatinine	1.4

Sodium chloride	7.4
Acidity (as lactic acid)	13.1
Nitrogen	10.8
Creatinine	8.7
Phosphorus	1.48

Calorics.—1.0 per gram; 28 per ounce.

Claims of Manufacturer.—The cubes are intended for flavoring a variety of dishes for the table and the preparation of bouillons, broths and soups.

PLEZOL TWIN BREAD

Manufacturer.—Frank Baker Bread Company, Lima, Ohio.

Description.—A white bread made by the sponge dough method (method described in The Journal, March 5, 1932, p. 817); prepared from patent flour, water, lard, dry skim milk, sucrose, salt, yeast, malt syrup and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	35.4
Ash	0.8
Fat	1.0
Protein (N × 6.25)	8.5
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	54.0

Calorics.—2.6 per gram; 74 per ounce.

Claims of Manufacturer.—A bread of good quality.

PORTOLA FRENCH STYLE SARDINES

(In Pure Olive Oil)

Manufacturer.—K. Hovden Company, Monterey, Calif.

Description.—Cooked immature sardines (Clupea caeruleus blue sardines) packed in olive oil.

Manufacture.—The fish are harvested as described for Portola Sardines (Pilchards) (The Journal, June 4, 1932, p. 1991) and immediately on landing are spread over tables, eviscerated, placed in a light brine for fifteen minutes to extract the blood, passed over a draper drier for sixty minutes and dried with hot air until the tails become brittle and the skin fairly dry, after which they are placed in thin layers in wire baskets and submerged in boiling cottonseed oil until thoroughly cooked. They are washed off with steam and fresh water to remove the oil, air cooled, and packed in olive oil in tins, which are processed under the control of the California State Board of Health as to temperature and time.

Analysis, Calorics and Claims of Manufacturer.—See these sections for Portola Sardines (Pilchards).

LAFER BROS. GOLDEN TABLE SYRUP

(85 Per Cent Corn Syrup, 15 Per Cent Refiners' Syrup)

Packer.—D. B. Scully Syrup Company, Chicago.

Distributor.—Lafer Brothers, Detroit.

Description.—A table syrup; a corn syrup flavored with refiners' syrup.

Manufacture, Analysis, Calorics, Claims of Manufacturer.—See these sections for Banner Blue Corn Syrup with Cane Flavor (The Journal, March 5, 1932, p. 817).

AN INTERPRETATION OF ANGINAL PAIN

Consideration of the clinical syndrome commonly described as angina pectoris must inevitably take into account the nature and primary location of the pain that is its most characteristic accompaniment. There have been numerous theories but, as a recent writer [1] has remarked, the striking diversity of these is sufficient proof of our inadequate knowledge of the subject. Often there are no demonstrable gross anatomic changes adequate to furnish an intelligible morbid anatomy of angina pectoris. It seems almost like an anomaly that a disorder ordinarily so easy of diagnosis should remain so perplexing in respect to the causes of the principal manifestations. In some quarters it has been held that anginal pain arises directly out of spasm of the coronary arteries in cardiac ischemia.[2] The more widely accepted view is that the pain is of muscular origin. It has been compared to the sensation of a muscle in a condition of severe cramp. In any event the problem of ischemia of the heart must be given some consideration, for it is known that pain can be brought about in various muscles when they are made to contract for some time during a diminished blood supply to them.

Spasm of the coronary vessels, intermittent claudication and anoxemia of the heart muscles have all been debated in relation to anginal pain. According to Keefer and Resnik,[3] a critical analysis of the theories that attribute angina pectoris to coronary spasm, to disease of the aorta or to myocardial exhaustion demonstrates that these views are open to such serious criticism that they become unacceptable; it can be shown, moreover, that anoxemia of the heart explains every characteristic of angina, including the likelihood of sudden death, which must be considered an integral feature of the condition. The percentage of instances in which conditions capable of producing anoxemia of the myocardium have been found in cases of undoubted angina is so high that the accuracy of the diagnosis in the few remaining instances seems open to question. Keefer and Resnik feel that an eclectic theory which admits a varied basis for angina should be abandoned. The angina pectoris of Heberden, they conclude, has but one cause, anoxemia of the myocardium.

Sir Thomas Lewis [4] of London has ventured to elucidate the debatable pain features by studying the analogous pain in ordinary muscular ischemia. The exercise used has been a simple gripping movement in the arm. The contractions are almost maximal, at the rate of one a second. The circulation is arrested during the exercise by means of a sphygmomanometer cuff, which is distended to a high pressure on the upper part of the arm. In an observation of this kind, pain begins from about twenty-five to forty-five seconds (or the same number of contractions) after the beginning of exercise; it develops progressively, increasing in intensity and rendering a continuation of exercise, still vigorously pursued, disagreeable or intolerable at about the seventieth second. The pain is continuous; it does not increase appreciably with the contraction of the muscle, and it does not subside with the relaxation. It is a smooth pain, gradually but constantly growing in intensity while exercise lasts. Thus, it is shown to be independent of the tension developed during the contraction of the muscle. The pain is not the result of cramp. The pain is determined by some chemical or physicochemical agency within the mass of muscle, for the factor underlying pain continues unchanged until the circulation is restored, whereupon it is promptly removed. In other words, in any contractile phenomena with the circulation free the change within the muscle fibers that ultimately underlies pain occurs, but pain does not develop, since the chemical factor cannot accumulate in the tissue spaces while these are under the influence of a free stream of blood.

According to Lewis's conclusions in his Billings Lecture at Chicago last fall, his observations [5] afford, for the first time, evidence for the belief that in ischemia pain arises from a working muscle and that the stimulus is derived from physiologic processes in the muscle fiber. Further, he states, if the characteristics of anginal pain and the various circumstances in which it arises and is influenced are closely considered in the light of these observations on somatic muscle, much that was previously obscure becomes plain to the understanding.

If, as Lewis postulates, anginal pain results from relative ischemia of the cardiac muscle, it may be provoked in distinct ways. Thus, it may be incited if the blood supply to the muscle becomes diminished, while the work done remains constant, or it may be provoked if the blood supply fails to increase adequately to the needs of a muscle that is called on to increase its work. The pain attending coronary occlusion originates from muscular ischemia. Spasmodic anginal pain is not due to strain on a structure such as the aorta but rather to relative ischemia. If one accepts the idea that attacks of anginal pain are brought about by relative ischemia of the muscle, according to Lewis, the relief of pain by nitrites may clearly come through a decrease of expenditure of energy, through an increase of blood supply, or by the joint effects of these two.

VITAMIN DEFICIENCIES AND NERVOUS SYSTEM LESIONS

Since Eijkman[1] showed that noninflammatory atrophic degeneration of the medullary sheaths of peripheral nerves occurred in hens fed on a diet of polished rice, it has been known that dietary deficiencies cause lesions of the nervous system. The factor responsible for this particular morphologic change was shown by Woollard[2] and others to be produced by a deficiency of vitamin B. Recently it has been found that what has heretofore been called vitamin B is really a mixture of at least two components; namely, the heat-labile antineuritic factor and a thermostable substance, the absence of which is thought to produce pellagra. Stern and Findlay[3] studied the changes in the nervous system of rats fed diets deficient in vitamin B (antineuritic component) and G (pellagra-preventive factor), respectively. In the first group of animals, they found chromatolytic changes in the ganglion cells of the spinal cord and early degeneration of the myelin of the peripheral nerves. In the second group, the changes consisted of swelling and vacuolization of the anterior horn cells of the spinal cord with the deposition in them of lipochrome pigment. Recently Zimmerman and Burack[4] have reported extensive demyelination of the peripheral nerves of dogs on a diet deficient in vitamin B, but they found similar though less marked changes in dogs that were entirely deprived of food except for adequate vitamin B complex in the form of vitavose. In animals that were partially or wholly on a diet deficient in vitamin G there were present degenerative lesions in the vermis cerebelli, the restiform bodies, and the fasciculus gracilis of the spinal cord, as well as demyelination of the peripheral nerves. Degeneration of the myelin sheaths of the median dorsal columns were found by Winkelman[5] in a case of human pellagra, and both Pentschew[6] and Langworthy[7] reported disseminated foci of demyelination in the spinal cords of similar cases.

It has been held that deficiencies in the vitamin B complex alone were responsible for lesions of the nervous system, but in 1931 Pappenheimer and Goettsch[8] described softenings in the cerebellum in chicks which they attributed to a lack of vitamin E. These lesions were in every way identical with those described by Zimmerman and Burack in their dogs subsisting on a diet deficient in vitamin G. Mellanby,[9] too, has reported observations on puppies deprived of vitamin A which developed degenerative changes in the form of demyelination of the nerve fibers of the spinal cord similar to the lesions seen in subacute combined degeneration. Furthermore, Hess[10] described focal degeneration of the lumbar cord in a case of infantile scurvy complicated by rickets.

If it can be assumed that, in the experimental work, lesions in the nervous system are produced as the result of single rather than multiple vitamin deficiencies, it must be granted that a large variety of vitamins play a specific part in the production of these lesions. Or, at least, any one of them can play an important contributory part to some factor, as yet entirely unknown, which is activated by them and alone produces the lesions. Which of these factors is responsible for the changes observed must await solution by the experimental method. It is more than likely that little in the way of positive proof can be adduced from the human cases of deficiency diseases associated with changes in the nervous system, as they almost certainly represent multiple deficiencies.

BASAL METABOLISM AND PUBERTY

In a discussion of the energy requirements of children, a recent volume on nutrition[1] remarks that the energy requirements of the body probably are better understood than any of the other specific nutritive requirements. Because energy is an old story, and because rare instances have been discovered among human beings of nutritional failure resulting from restricted choice of foods even when the total quantity was plentiful, there has been a tendency in some quarters to regard calories as of no further importance. It requires only the stress of some major calamity such as war, flood or an economic emergency, however, to revive the realization that supplying enough to eat to a population means a sufficiency of calories as well as that freedom of choice which is the everyday guaranty of quality (vitamins, minerals, amino-acids). Considerations of energy requirements start logically from a discussion of the basal metabolism, which has been defined as that level of metabolism which prevails when all modifying factors are producing their minimal effects. These factors, as usually stated, are food, work and temperature.

[1] Growth and Development of the Child: Part III. Nutrition, White House Conference on Child Health and Protection. New York, Century Company, 1932.

A controversy has arisen of late regarding the alleged influence of racial characters on the basal metabolism of adults. A recent writer[1] has remarked that the almost uncanny agreement found in applying the formulas of surface area to the basal metabolism of individuals of widely different body form, widely different proportions of body fat, and so on, have served to inhibit rather than stimulate interest in the effects of minor differences. These may be assumed to include the hereditary factors that affect body size and proportion, those which affect nervous organization, and those which produce a tendency to leanness or fatness, aside from the endocrine functions. There is more general agreement that adolescent children have a "distorted" energy requirement. Part of this is undoubtedly attributable to the unusual activity of growing children. Even for the basal metabolism, however, Du Bois,[2] who has devoted much attention to the subject, believes that there is a rise in basal metabolism before puberty with a subsequent fall; but the proof will come, he concludes, only when a number of individual boys and girls are studied every year, or, better, every six months between the ages of 10 and 16 years.

A contribution to the subject has lately been reported from the pediatric service of the Mount Sinai Hospital in New York by Topper and Mulier.[3] The basal metabolism of twenty-eight girls and ten boys from 10 to 16 years of age was studied at intervals of from six months to a year over a period of from one to four years. It was found that there was an increase in the basal metabolic rate in the prepubescent period, reaching its maximum around the time when the menses were established in girls and sexual maturity in boys, with a subsequent decline afterward. There was no uniformity in the height of the increased metabolism or in the duration of the increase. Some of these children had no other symptoms of an overacting thyroid gland. Others presented such symptoms as an enlarged thyroid gland, tremor, nervousness, vasomotor instability, cardiac murmur and tachycardia—all of which symptoms disappeared as the basal metabolic rate returned to the previous normal level, when puberty was well established.

Topper and Mulier believe that an increased basal metabolism is physiologic during pubescence. This increase coincides with the physiologic age rather than with the chronological age and occurs earlier in girls than in boys, coincident with their earlier pubescence. As there seems to be an individual variation in the height and duration of the increased metabolism, it makes the adoption of normal standards difficult for this important age period. The increased basal metabolism may be associated, according to the New York pediatricians, with symptoms simulating organic heart disease or, more especially, exophthalmic goiter. Therefore, they conclude, in evaluating high metabolic figures at this period, the clinical manifestations of pubescence have to be considered. Exophthalmic goiter is rare before puberty and should not be confused with the physiologic overactivity of the thyroid gland in pubescence, which is temporary and the prognosis of which is excellent.

Current Comment

THE DILEMMA OF LISTERINE

When Congress, which on occasion has attempted to practice medicine, enters into any medical field it is likely to confuse the situation somewhat. Perhaps the good congressional doctors were not aware, when they were concerning themselves with budget balancing, of the difficulties they were conferring on some of America's leading industrial concerns; for example, the Lambert Pharmacal Company, concocters of Listerine. Not long ago The Journal reported the results of the study of this product made by the A. M. A. Chemical Laboratory and the Bureau of Investigation. As a result of this study the opinion was stated that the product cannot be considered in any sense of the word a real germicide and that the claims made for it were hardly justified by available evidence. Now, however, the manufacturer finds himself in a position where it is necessary for him to determine exactly what the product really is good for. Various preparations are taxed according to their uses. The product called Listerine is sold largely as a gargle for sore throats; used in this manner, it is a medicinal agent. Under the new revenue law, medicinal agents are free from tax. However, in order to combat the campaign put forth on behalf of Pepsodent Antiseptic by Amos and Andy, in recent days Listerine has also been widely advertised as a mouth wash. In fact, the technical term "halitosis" was rescued from the musty archives of medical dictionaries and made a byword—and a reproach—by the Listerine manufacturers before Pepsodent appeared on the scene. Mouth washes, under the new revenue law, are taxable at 5 per cent. Furthermore, it seems to have occurred to the agency which promotes Listerine that it has usefulness—at least from the advertising point of view—as an after-shaving lotion and that its virtues for the control of dandruff are extraordinary. By such usage the product becomes a cosmetic or toilet article. The toilet goods tax is 10 per cent. What a dilemma! If the

[3] Topper, Anne, and Mulier, Hannah: Basal Metabolism of Normal Children, Am. J. Dis. Child. 43:327 (Feb.) 1932.

Treasury Department asserts that Listerine is a toilet article, it will have to pay 10 per cent; if it is a mouth wash, it will have to pay 5 per cent, and if it is a medicinal agent, it can get off without a tax. We can assure the Treasury Department, as a result of the investigation carried on by the Chemical Laboratory of the American Medical Association, that as a medicinal agent it is not potent enough to be considered seriously. Whether it pays 5 per cent or 10 per cent is for the authorities to decide, but if it really is to be helpful—although somewhat indirectly—to the people who buy it, the bigger the tax the better!

Association News

TIME OF MILWAUKEE SESSION

The Eighty-Fourth Annual Session of the American Medical Association will be held in Milwaukee, June 12 to 16, 1933.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 10:45 to 10:50 a. m. over Station WBBM (770 kilocycles, or 389.4 meters). The Columbia chain program has been discontinued for the present.

The subjects for the week are as follows:

July 11. Food and Food Advertising.
July 13. Your Heart.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 10:45 to 11 over Station WBBM.

The subject for the week is as follows:

July 16. Rheumatism.

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Society News.—A symposium on syphilis constituted the program of the Alameda County Medical Society, June 20; the speakers were Drs. Harry J. Templeton, Gertrude Moore, Charles B. Fowler, Oakland, Clifford W. Mack, Livermore, and Archie A. Alexander, Oakland.

Quarantine on Mussels.—Persons who go to beaches along the northern California coast are warned not to eat mussels because of the danger of contracting mussel poisoning, states a recent bulletin of the state department of health. The department prohibits the sale or offering for sale of mussels gathered within the coast area from Monterey County to the Klamath River in Del Norte County during the period May 16-September 30. Examinations of mussels are made at stated intervals throughout the year. It has been determined that these shellfish lose most of their toxicity during the winter months. In the spring they become more toxic, reaching a maximum state of toxicity about the middle of July and gradually becoming less toxic until late fall. The bulletin of the department states that the poisonous qualities are higher at the present time than they are ordinarily at this season of the year. In 1927, there were 102 cases of mussel poisoning with six deaths reported; in 1929, fifty-five cases with four deaths; in 1930, one case, and in 1931, two cases.

CONNECTICUT

Personal.—Lafayette B. Mendel, Ph.D., Sterling professor of physiological chemistry, Yale University School of Medicine, New Haven, received the honorary degree of doctor of laws from Western Reserve University at its recent commencement.——Dr. Winthrop M. Phelps has been appointed professor of orthopedics at Yale University School of Medicine, New Haven.

DISTRICT OF COLUMBIA

Personal.—Dr. Daniel L. Borden was elected president of the alumni association of George Washington University, June 11. Dr. Frederick A. Reuter was elected a vice president of the association, representing the school of medicine.——Dr. John W. Wilce, former football coach at Ohio State University, has been appointed a medical examiner for the aeronautics branch of the U. S. Department of Commerce.

Cancer Hospital for Women.—Construction of Washington's first hospital for the treatment and care of women with cancer will be started soon on the grounds of Garfield Memorial Hospital with funds provided under the will of R. T. Warwick, the Washington *Star* reports. More than $300,000 was bequeathed in the will, to be administered by the Washington Home for Foundlings. An agreement has been reached between the trustees of the home and the hospital, whereby the cancer institution will occupy a portion of the grounds of Garfield Hospital and have available for its use much of the hospital equipment. It was said that a considerable amount of the money will be spent in acquiring equipment necessary for the treatment of cancer alone. Efforts will be made later, it was said, to extend the facilities of the new hospital by seeking additional funds in order that it may be enlarged and better equipped.

ILLINOIS

Chicago

Personal.—Dr. Chauncey C. Maher has been appointed assistant professor of medicine at Northwestern University Medical School, effective June 1.——Dr. Cyrille Vermeren, Belgian consul since 1915, has been awarded the Cross of Officer of the Order of Leopold and promoted to the rank of consul-general, the newspapers recently announced. Dr. Vermeren was a practicing physician in Chicago for years.

Examination of School Children Abandoned.—With the failure of the city to renew the appropriation for twenty-five school physicians and nurses, the physical examinations of school children have been discontinued, newspapers report. The Municipal Tuberculosis Sanitarium has been paying these physicians for this work. The newspapers further reported that the health department, while maintaining a few physicians to handle contagion in the schools, has not conducted physical examinations among the school children for the last fifteen years.

The New Provident Hospital.—Simple ceremonies marked the laying of the corner-stone of the new home of the Provident Hospital, June 14, which is the building formerly occupied by Chicago Lying-In Hospital, now being remodeled. In a cooperative program between the hospital and the University of Chicago, it is planned to develop this institution into a medical education center for Negroes. This program includes the care of the sick, clinical instruction for medical students, an increase in the number of internships for Negro physicians, graduate medical training, opportunities for Negro students for teaching and research. In 1930 a fund of $3,000,000 was subscribed for the development of this center. Provident Hospital, now at 16 West Thirty-Sixth Street, was founded in 1890 and has since been an important center for medical work among Negroes of the community. Rear Admiral Norman J. Blackwood, medical corps, U. S. Navy, retired, has been appointed medical director.

INDIANA

Personal.—A bronze tablet was unveiled, May 31, by members of the Methodist Hospital Staff Society, Indianapolis, in memory of Dr. Charles L. Cabalzer.——Dr. Jesse E. Nixon, Portland, has been appointed health officer of Jay County, succeeding Dr. William H. Walker, Portland.——Dr. Frank C. Walker has been promoted to professor of diseases of women and head of the depar [illegible] liana University School of Medicine,

Dr. Waters Honored.—Dr. Samuel C. Waters, Middletown, was presented with a life membership in the Henry County Medical Society, June 15, at a dinner given by the society in his honor. Dr. Edgar S. Ferris, Newcastle, presided as toastmaster. Speakers included Drs. Hugh A. Cowing, Muncie, and Clifford E. Canaday, Newcastle, Frank W. Cregor and

Homer H. Wheeler, Indianapolis, and Mr. Thomas A. Hendricks, secretary of the state medical society. Dr. Waters has practiced medicine for more than fifty years. As The Journal goes to press, an account is received of the sudden death of Dr. Waters in his office, June 22.

Society News.—Dr. Millard F. Arbuckle, St. Louis, addressed the Vanderburgh County Medical Society, June 14, on "Extraction of Foreign Bodies from the Lungs."——The Whitley County Medical Society was addressed, June 14, by Dr. Ralph W. Elston, Fort Wayne, on "Surgical Diseases of the Abdomen of Children."——Dr. Robert M. Moore, Indianapolis, addressed the Carroll County Medical Society in Bringhurst, June 10, on congestion of the heart and angina pectoris. ——At the May 13 meeting of the Hancock County Medical Society, Dr. Matthew Winters, Indianapolis, spoke on pediatrics.——The Gibson County Medical Society heard a paper on "Gastro-Intestinal Infection in Children" in Princeton, June 13, by Dr. Paul R. Boren, Poseyville.

IOWA

Conference on Child Development.—The sixth annual Iowa State Conference on Child Development and Parent Education was held at Iowa City, June 21-23. Cooperating with the Iowa State Council for Child Study and Parent Education were the Iowa Child Welfare Research Station, the Extension Divisions of Iowa State College and the State University of Iowa and the state teachers' college. Topics discussed included "Child Health and Protection in the State of Iowa," Dr. Fred Moore, Des Moines, and "Mental Hygiene in the Community and State; Mental Hygiene and the Individual Child," Dr. George K. Pratt, New York.

Dr. Evans Honored.—The Webster County Medical Society gave a dinner, April 28, in honor of Dr. Robert Evans, who has practiced for forty years in Fort Dodge, and who, on the forty-fifth anniversary of his graduation in medicine, announced his retirement from practice. Dr. Sumner B. Chase presided as toastmaster at the program which followed the dinner. Dr. William W. Bowen, president, Iowa State Medical Society, with whom Dr. Evans has been associated in practice for many years, reviewed the more noteworthy incidents of their partnership. Other speakers were Drs. Philip B. McLaughlin, Sioux City; Michael J. Kenefick, Algona; Prince E. Sawyer and William Jepson, Sioux City; Channing G. Smith, Granger, retiring president of the state medical society; Edward L. Rohlf, Waterloo, and Howard D. Gray, Des Moines.

Illness Among Button Workers.—Five cases of a condition diagnosed as yellow atrophy of the liver recently occurred at Fort Madison among the personnel of a button factory, with three fatalities. A meeting of physicians disclosed, however, that a total of sixteen cases had been reported since November, 1928, with five deaths. All the cases had occurred in men employed in the button factory during the winter months. The work at the plant involved consists solely of sawing blanks from oysters and clam shells, which are shipped elsewhere to be finished into buttons. The shells are obtained from Texas, Mexico and Illinois. At a meeting of the Fort Madison City Medical Society, it was generally agreed that in view of the absence of any tangible evidence of metallic poisoning, the disease must be considered of an infectious nature. Arrangements have been made for prompt removal to the hospital of the State University of Iowa if another case should develop.

Society News.—A symposium on anesthesia was held at the meeting of the Des Moines Academy of Medicine and the Polk County Medical Society, May 31; the speakers were Drs. John Connell, E. Parish Lovejoy and John Russell.——Dr. Arthur Steindler, Iowa City, addressed the Scott County Medical Society, May 11, on "Periarthritis of the Shoulder."——Dr. Edward J. Stieglitz, Chicago, addressed the eighteenth annual meeting of the Iowa Medical Directors Association on "Prognosis in Hypertension," May 26, in Des Moines. This association is composed of medical directors of all old line life insurance companies in Iowa. Dr. Loren K. Meredith was elected president.——At a recent meeting of the Cass County Medical Society, the speakers were Drs. Reu L. Barnett and Harvey A. Johnson, Atlantic, on Raynaud's disease and thromboangiitis obliterans, respectively.——A symposium on neurosyphilis was presented before the Fayette County Medical Society at Fayette, May 10, by Drs. Robert A. Stewart and George Boody, Independence.——Dr. Emma M. Ackerman, Sioux City, was recently elected president of the Iowa Society for Medical Women.——Dr. Ira N. Crow, Fairfield, was elected president of the Des Moines Valley Medical Association at its recent annual session, and Dr. Edward B. Hoeven, Ottumwa, was reelected secretary.

KENTUCKY

Cancer Death Rate Decreases.—For the first time since 1925 the cancer death rate in Kentucky shows a decrease, according to statistics published by the state board of health. The rate for 1931 was 59.8, compared with 71.2 in 1930. The total death rate for the state was 11 per thousand of population, said to be the lowest except one during the past ten years. Heart disease was the principal cause of death, though there were 223 fewer deaths from that cause in 1931 than in the previous year. The infant mortality rate rose from 66.5 to 68.6, but the increase was attributed to a drop in birth registration, as there were only 24 more deaths. The birth rate recorded was 21.8 per thousand.

LOUISIANA

District Society Organized.—Physicians of the second congressional district, exclusive of Orleans Parish, formed the District Medical Society at a meeting, June 5, in Hahnville. The parishes included in the district are St. Charles, St. James, St. John and Jefferson. Officers elected are Drs. Joseph S. Kopfler, Kenner, president; Louis T. Donaldson, Hahnville, vice president, and Lionel O. Waguespack, Vacherie, secretary. Assisting in the organization of the society were Drs. Leon J. Menville, New Orleans, president, state board of medical examiners, and Paul T. Talbot, New Orleans, secretary, state medical society, both of whom made addresses.

Society News.—Speakers before the Fifth District Medical Society in Monroe, June 14, included Drs. James B. Vaughan, on "Present Economic Situation as It Affects the Medical Profession," and Melville W. Hunter, on "Differential Diagnosis of Early Pulmonary Tuberculosis."——The Seventh District Medical Society was addressed at Lake Charles, June 15, by Dr. Oscar W. Bethea, New Orleans, on angina pectoris. ——At a scientific meeting of the Orleans Parish Medical Society, June 13, speakers included Dr. Sidney M. Copeland on hypertension; Sidney L. Tiblier, D.D.S., "Modern Conceptions of Diagnosis of Oral Pathology," and Dr. Leon J. Menville, "Radiation Therapy of Toxic Goiter."——Dr. Charles A. Bahn, New Orleans, was elected president of the Louisiana Society for the Prevention of Blindness at its recent annual meeting.

MAINE

Society News.—Dr. Herman C. Pitts, Providence, R. I., addressed the Cumberland County Medical Society recently on "Uterine Cancer."——Speakers before the Kennebec County Medical Association at Winthrop, June 2, were Drs. William J. O'Connor, Augusta, and Adam P. Leighton, Jr., Portland, on gastric ulcer and gynecology, respectively.——The Washington County Medical Society was addressed in Eastport, May 26, by Drs. Conrad Wesselhoeft, Boston, on "Acute Anterior Poliomyelitis."——The York County Medical Society was addressed, June 8, in Saco, by Drs. Earl S. Hall, Portland, and Varaztad H. Kazanjian, Boston, on "Newer Aspects and Changes in Treatment of Fractures" and "Oral Surgery," respectively.

MARYLAND

Personal.—Yale University recently conferred the degree of doctor of literature on Dr. Fielding Hudson Garrison, librarian of the William H. Welch Library, Johns Hopkins University School of Medicine, Baltimore.

Case of Leprosy.—A case of leprosy was recently reported to the Baltimore health department. The patient, a woman, in the northeastern section of Baltimore, has been isolated at Sydenham Hospital pending her transfer to a leper colony by the U. S. Public Health Service. She has been living in Baltimore for a number of years.

Special Public Health District.—Creation of a special public health district in Baltimore for the training of public health workers has been made possible by a recent grant of about $25,000 for two or more years from the Rockefeller Foundation, through the School of Hygiene and Public Health of Johns Hopkins University, Baltimore. The only change in the existing methods of health work in the district, which will comprise the sixth and seventh wards in eastern Baltimore, will be the appointment of a full time physician as director of a branch of the city health department. The director will supervise the health needs of the district and lecture on public health work to students in the school of hygiene. The interest of Johns Hopkins University in the district will be chiefly in the facilities it will afford to the school of hygiene and public health for practical instruction of students and for investigations in the field of public health.

MASSACHUSETTS

Personal.—The degree of honorary doctor of medicine has been conferred by the University of Amsterdam on Dr. Harvey Cushing, until recently Moseley professor of surgery, Harvard University Medical School, Boston. Dr. Cushing recently received the honorary degree of doctor of science from Northwestern University, Chicago.——The University of Würzburg conferred the degree of doctor of medicine honoris causa on Francis G. Benedict, Ph.D., Boston, director of the Nutrition Laboratory of the Carnegie Institution, May 2.

Testimonial Dinner.—In recognition of the services of four senior members of the faculty of Boston University School of Medicine and the staff of Massachusetts Memorial Hospitals, more than 100 of their colleagues gathered at a dinner in their honor in the University Club, Boston, June 22. The physicians honored were Drs. Joseph Emmons Briggs, professor of surgery; Alonzo G. Howard, professor of orthopedic surgery; Wesley T. Lee, professor of dermatology, and Clarence H. Dobson, assistant in medicine. Dr. Briggs has been connected with the university since his graduation at the institution in 1890. Dr. Howard was graduated from the university in 1895, and Dr. Lee in 1898, and both men became associated with the school immediately after graduation. Dr. Dobson graduated from Hahnemann Medical College, Philadelphia, in 1897, and has been at Boston University School of Medicine since 1921. Dr. Henry M. Pollock, superintendent, Massachusetts Memorial Hospitals, was toastmaster at the dinner. Speakers included Henry S. Grew, president of the board of trustees of the hospitals; E. Ray Speare, treasurer of the university trustees; Dr. Alexander S. Begg, dean of the medical school; Dr. Edward S. Calderwood, physician-in-chief of the hospitals, and Dr. Charles T. Howard, surgeon-in-chief.

NEBRASKA

Fifty Years in Practice.—Dr. John Prentiss Lord, Omaha, and Dr. Harry Hapeman, Minden, are celebrating this year the completion of fifty years of medical practice. Both were born in Illinois, both attended Rush Medical College, Chicago, from which they were graduated in 1882, and they have remained lifelong friends, according to the *Nebraska State Medical Journal*. Dr. Hapeman came to Nebraska in 1881 and Dr. Lord in 1886. Dr. Lord has been professor of orthopedic surgery at Nebraska University College of Medicine since 1913. Before assuming that position, he was professor of surgery at Creighton University School of Medicine for twenty years. He has been president of the Nebraska State Medical Association (1910-1911) and was chairman of the Section on Orthopedic Surgery of the American Medical Association in 1927.

NEW JERSEY

Personal.—Dr. Theobald Smith, Princeton, director emeritus of the department of animal pathology, Rockefeller Institute for Medical Research, received the honorary degree of doctor of veterinary medicine from the University of Giessen at the hundredth anniversary of the granting of veterinary degrees.

Measures to Curb Rabies Adopted.—The state department of health recently adopted a resolution requiring local boards of health to report once a week the occurrence of cases of rabies in dogs. Because of an unusual prevalence in Essex County, the department called on the local authorities there to invoke emergency measures. Dr. Jesse Lynn Mahaffey, state director of health, urged the local boards of health to enforce the regulations requiring dogs suspected of having rabies to be killed or confined for at least six months. Other laws invoked require the reporting of dog bites and the confining of animals that have attacked or bitten any person, the licensing of dogs, and the elimination of unlicensed dogs. In addition, Dr. Mahaffey suggested that dogs, when not restrained to their owners' premises or in leash, be muzzled and, finally, that the public be advised of the prevalence of the disease among dogs and urged to cooperate in its control.

NEW YORK

Society News.—Dr. Chevalier Jackson, Philadelphia, addressed physicians of northern New York and those who are attending the Trudeau School for Tuberculosis at a meeting, June 3, at the National Variety Artists' Sanatorium, Saranac Lake.——Dr. Royd Ray Sayers, Washington, D. C., addressed the Medical Society of the County of Monroe, Rochester, May 17, on "Physical Examinations of Workers Engaged in Hazardous Occupations."

Art Exhibit.—A collection of water colors, bas-reliefs, masks and modeled figures by Dr. Konrad E. Birkhaug, associate professor of bacteriology, University of Rochester School of Medicine, has recently been shown at the Art Center in Rochester. The water colors depicted scenes in many parts of North America and Europe. Dr. Birkhaug has recently left for Europe to spend a year studying at the Pasteur Institute in Paris and he expects to spend some time in the study of art as well.

Annual Health Conference.—The annual conference of health officers and public health nurses of the state was held in Saratoga Springs, June 28-30. The following speakers appeared on the program, among others:

Dr. Frederick F. Russell, New York, "Evolution and Trends of Health Organization."
Dr. Walter T. Harrison of the U. S. Public Health Service, "Toxoid and Its Advantages Over Toxin-Antitoxin."
Dr. Albert VanderVeer, New York, "Hay Fever as a Public Health Problem."
Dr. Herman G. Weiskotten, Syracuse, "Developments in Education in Preventive Medicine and Public Health."
Dr. Frank W. Laidlaw, Middletown, "Studies on the 1931 Poliomyelitis Outbreak: A Preliminary Report."

New York City

Hospital News.—A marine roof was opened, May 26, on the new wing of the New York Polyclinic Medical School and Hospital, not at the New York Postgraduate Medical School and Hospital, as mentioned in THE JOURNAL, June 25.

OHIO

Society News.—William J. Burns, executive secretary, Wayne County Medical Society, Detroit, addressed the annual meeting of the Medical Bureau of Akron, June 14, on medical economics.——Roentgen-ray equipment is being installed at the health center operated by the health department of Cincinnati as the result of a gift of $10,000 from Charles F. Williams, president of the Western and Southern Life Insurance Company, Cincinnati. Dr. Henry Kennon Dunham will have charge of the interpretation of films. The department expects to use the equipment especially in the campaign against tuberculosis.

OKLAHOMA

Graduate Course.—Physicians of eastern Oklahoma are attending a special course dealing with degenerative diseases during the four weeks from June 13 to July 15. Meetings are held once each week in a circuit of six cities. Among the instructors are Drs. Isaac I. Lemann, New Orleans; Elsworth S. Smith, St. Louis; Joseph T. Martin, Arthur W. White, Harry Wilkins, Thomas C. Lowry and Arthur B. Chase, all of Oklahoma City, and James B. McElroy, Memphis.

OREGON

Licenses Restored and Revoked.—The license of Dr. Wilber H. Thompson, Elgin, which was revoked Nov. 20, 1931, for violation of the narcotic law, was restored, May 31, on his promise to abstain from the private use of narcotics. The license of Dr. Joseph A. Wonderlick, La Grande, revoked Nov. 19, 1931, for alleged abortion, was restored, May 31. The state board of medical examiners also reports that the license of Dr. Norman C. Hampton, Portland, was revoked, May 31, for unprofessional conduct.

Society News.—Dr. Milton Earl Wilson, Coquille, addressed the Coos County Medical Society, Marshfield, in May, on poisonous plants.——The Portland Pediatric Society was organized in March.——Drs. William K. Livingston, Portland, and Frank K. Power, Salem, addressed the Polk-Yamhill-Marion Counties Medical Society, McMinnville, May 3, on "Buerger's Disease" and "Retention in the Urinary Bladder," respectively.——Dr. Martín S. Sichel addressed the Portland City and County Medical Society, May 4, on trichomonas vaginalis.

PENNSYLVANIA

Symposium on Dental Caries.—A symposium on the cause and nature of tooth decay was held at the Frick Training School, Pittsburgh, June 23, under the auspices of the Pittsburgh section of the International Association for Dental Research. H. Edmund Friesell, D.D.S., dean, University of Pittsburgh School of Dentistry, and John J. Enright, Ph.D., of Mellon Institute for Industrial Research, presented the results of a nine-year study of tooth decay. The following speakers discussed these contributions: William J. Gies, Ph.D., Columbia University, New York; Dr. Edward H. Hatton, Northwestern University, Chicago; Russell W. Bunting, D.D.Sc., University of Michigan, Ann Arbor; Major Fernando E. Rodriguez, U. S. Army Dental Corps, and Theodor Rosebury, D.D.S., Columbia University, New York.

Philadelphia

Honorary Degrees.—At the commencement ceremonies of the University of Pennsylvania, June 22, the honorary degree of doctor of medicine was conferred on Alfred Newton Richards, Ph.D., professor of pharmacology in the school of medicine. Dr. William Pepper, dean of the school of medicine, and Dr. Barton Cooke Hirst, emeritus professor of obstetrics, received the honorary degree of doctor of science, as did Harlow Shapley, Ph.D., director of the Harvard Observatory, Cambridge, Mass., who delivered the commencement address.

Personal.—The honorary degree of doctor of science was conferred on Dr. Ross V. Patterson, dean of Jefferson Medical College, by Colgate University, Hamilton, N. Y., June 13.——Dr. Willard H. Kinney has been elected president of the Philadelphia Urological Association.——The intern prize of $100 offered by the medical board of the Philadelphia General Hospital has been awarded to Dr. John K. Caldwell for a paper entitled "The Correlation of the Van Den Bergh Reaction and the Icterus Index Test."——Dr. Theodore H. Mendell, resident physician at Mount Sinai Hospital, has been awarded the fellowship offered by the hospital association for graduate study abroad.

TEXAS

State Board Warns Against Impostors.—The Texas State Board of Medical Examiners has sent to chambers of commerce throughout the state a letter asking the cooperation of these organizations in warning the public against medical fakers. The letter urges that any stranger who treats or offers to treat a human being for a disease or disorder, mental or physical, and charge therefor, be required to show the annual registration permit issued by the board or to prove that he has a license on record in the office of the district clerk in the county in which he proposes to practice.

WASHINGTON

Society News.—Drs. Dorrell G. Dickerson and Adolf J. Drtina, Seattle, addressed the Thurston-Mason Medical Society at Shelton in May on "Relief of Headaches" and "Common Afflictions of the Heart and Their Treatment," respectively.——The Yakima County Medical Bureau has recently been organized with Dr. William K. Cocklin as president. The bureau will handle questions arising in industrial practice, such as signing contracts with industrial plants. Under its system, laborers will be able to select their own physicians from the membership of the bureau.

WEST VIRGINIA

Filipino Presents Forged Diploma.—Forged credentials were said to have been used by Joseph del Rosario y Danque, New York, formerly of Manila, to obtain permission to take the West Virginia examinations for license to practice medicine in July and again in November, 1931, according to information received from the University of Santo Tomas, Manila, from which he claimed graduation. He presented a diploma from the Manila university and because the time before the examination was too short in which to obtain verification from the authorities there he was admitted on condition that the necessary documents would be forthcoming. He failed, however, on both examinations. Later correspondence between the Council on Medical Education and Hospitals of the American Medical Association and the University of Santo Tomas revealed that del Rosario attended the school only three years, having left in 1927. The diploma, which the university secretary declares is forged, states that he was graduated, April 10, 1928.

GENERAL

Delegates to Tuberculosis Conference.—Official delegates designated by the United States government to take part in the eighth conference of the International Union Against Tuberculosis in Amsterdam in September are Drs. William Charles White, Washington, D. C.; Kendall Emerson and S. Adolphus Knopf, New York; Stephen J. Maher, New Haven, Conn.; Eugene L. Opie, Philadelphia; Stuart Pritchard, Battle Creek, Mich.; Willard B. Soper, West Haven, Conn., and Hugh de Valin of the U. S. Public Health Service.

Study of Air Conditions.—Basic data on the condition of the air in the average American city as to the presence of soot, ash, sulphur, lead, iron and carbon monoxide is to be obtained through a study recently initiated by the U. S. Public Health Service. It will be extended over two years in Washington, Baltimore, Philadelphia, New York, Boston, Buffalo, Cleveland, Detroit, Chicago, Pittsburgh, St. Louis, San Francisco, Los Angeles and New Orleans. It is expected that the field part of the study will be completed sometime during 1933.

Board of Otolaryngology Emphasizes Standards.—The five societies whose representatives make up the American Board of Otolaryngology have approved at their respective annual sessions for 1932 a resolution commending the work of the board and requesting state boards of medical examiners to keep in mind its standards when formulating any regulation or classification of physicians claiming to be specialists in this field. The resolution points out that standards for the practice of the specialty have been distinctly elevated and graduate instruction in the United States and Canada has been improved as a result of the voluntary appearance before the board of candidates for certification. Numerous regional special societies, hospital staffs and medical school faculties have prescribed the board's certificates as prerequisites to membership. The societies which cooperate in this work are the American Laryngological Association, American Otological Association, American Laryngological, Rhinological and Otological Society, American Academy of Ophthalmology and Otolaryngology and the Section on Laryngology, Otology and Rhinology of the American Medical Association.

Prevalence of Cerebrospinal Meningitis.—Following the epidemic outbreaks of cerebrospinal meningitis during the years of the World War, the incidence of the disease decreased for several years, but a decided upward trend has been observed since 1922, according to a study made by the health section of the League of Nations. The highest point was reached in 1929 in the countries of south central Europe but not until 1931 in England, Scotland and the Netherlands. In England, the number of cases increased from 666 in 1930 to 2,160 in 1931 and in the first quarter of 1932, 733 cases were reported. In the United States the maximum was reached in 1929, when more than 10,000 cases were reported. The decrease is evident in a comparison between the number of cases reported in January and February, 1932 (320 and 335, respectively), and the figures for the same months of 1931 (595 and 588, respectively). The disease has increased steadily since 1923 in Russia, though part of this increase is attributed to improved reporting. A serious epidemic has recently been reported from lower Egypt, beginning in November, 1931, and reaching as high as 637 cases per week in March. Meningitis has been endemic in the large ports of the Far East for some years with sporadic epidemics. Shanghai had an outbreak of 1,187 cases, with 403 deaths in 1929, and severe outbreaks have occurred this year in Hong-Kong and Macao.

Society News.—The Society for Experimental Biology and Medicine at its recent annual meeting elected the following officers: president, Dr. Alphonse R. Dochez, New York; vice president, Dr. Eugene L. Opie, Philadelphia, and secretary, Abraham J. Goldforb, Ph.D., New York.——At the annual meeting of the American Gynecological Society, Quebec, June 1, Dr. Floyd E. Keene, Philadelphia, was elected president; Dr. William B. Hendry, Toronto, vice president; Dr. George W. Kosmak, New York, treasurer, and Dr. Otto H. Schwarz, St. Louis, secretary.——Dr. James V. May, Boston, was elected president of the American Psychiatric Association at its meeting in Philadelphia, June 3, and Dr. Clarence O. Cheney, New York, secretary.——The American Urological Association at its annual meeting in Toronto, June 1, elected the following officers: Drs. Nathaniel P. Rathbun, Brooklyn, president-elect; George R. Livermore, Memphis, president, and Gilbert J. Thomas, Minneapolis, secretary.——The American Society for Cancer Research has recently elected officers as follows: Drs. Edward B. Krumbhaar, Philadelphia, president; Ward J. MacNeal, New York, vice president, and William H. Woglom, New York, secretary.——The annual meeting of the American Occupational Therapy Association will be held in Detroit, September 13-15.——Dr. John H. Peck, Des Moines, Iowa, was elected president of the National Tuberculosis Association at the annual meeting in Denver, June 8. Vice presidents are Drs. Lewis J. Moorman, Oklahoma City, and Harry L. Barnes, Wallum Lake, R. I.; secretary, Dr. Charles J. Hatfield, Philadelphia, and treasurer, Henry B. Platt, New York.——The Southern Interurban Gynecological and Obstetrical Society held its second annual meeting in New Orleans, May 7. The following officers were elected: Dr. John W. Turner, Atlanta, president; William T. Pride, Memphis, vice president, and Percy H. Wood, Memphis, secretary. Among the speakers were Drs. Walter T. Dannreuther, New York, on "The Use of Radium in Gynecology in Other Conditions Than Cancer," and C. Jeff Miller, New Orleans, "Conservative Management of Pelvic Infections."

FOREIGN

Trachoma Prize Awarded.—Dr. Ugo Lumbroso, Tunis, and Dr. J. Taboriski, Palestine, have been awarded the International Trachoma Prize of 2,000 Swiss francs, offered by the royal Hungarian minister of public welfare and labor (The Journal, April 11, 1931, p. 1243) for an essay on the etiology of trachoma. Honorable mention was given to Dr. Cattaneo, Sassari; Dr. P. Olitsky, New York; Rotth and Kanyo, Budapest, and C. Trapezontzewa, Moscow, it was reported.

Courses in Berlin.—Graduate courses in medicine arranged for the autumn by the Lecturers Association and the Kaiserin Friedrich-Haus of Berlin in association with the faculty of the University of Berlin include the following: internal medicine, October 17-29; tuberculosis, October 10-15; general medicine, October 10-15; urology, September 26-October 1; medical psychology and psychotherapy, October 17-22; intrathoracic diseases, October 17-21. Information may be had from Kaiserin Friedrich-Haus, Berlin N.W. 7, Robert Koch-Platz 2-4.

British Prize Competition. — The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money prize of 50 guineas, is again offered to members of the British Medical Association for essays on personal observations and experiences collected in the course of general practice. Essays are to be submitted before December 31, and the prize will be awarded at the 1933 meeting of the association. This award was established by the council of the British Medical Association for the promotion of systematic observation, research and record in general practice.

Council to Regulate Medical Advertising.—The government of Yugoslavia is reported to have decreed that all medical advertising must be scrutinized by the permanent expert council of the ministry of social welfare and public health before it can be placed in newspapers and magazines. The advertiser must submit to the council the text of the advertisement, with any illustrations to be used, together with a copy of the permit to sell in Yugoslavia and any other data serving to classify the medicine, together with the prescribed fees, which amount to about $30. He must in addition bind himself to supply to the council the first copy or issue of the paper or magazine and subsequently one copy of the newspaper each month and a copy of the magazine every three months. On all printed advertisements there must appear this legend: "Approved by the Ministry of Social Welfare and Public Health, S. Number ——" and the date. These regulations apply to "every individual or firm, domestic or foreign, having the right to produce, sell or import into the country medicines and medicinal specialties, and wishing to advertise these in the daily papers or in any other manner," according to the report.

Society News. — The headquarters of the International Congress on Biliary Lithiasis, which is to be held at Vichy, France, September 19-22, announces that the principal French railways have extended the time during which the vouchers for special rates may be used from fifteen to thirty days. They can now be used for the whole month of September, thus allowing physicians attending the congress to remain in France longer if they desire. The latest date for receiving applications for membership in the congress is August 1.——A society for the study of the physiology and pathology of the voice and speech was founded in Paris, May 9, to be known as the "Société Française de Phoniatrie." The officers are Professor Moure, president; Dr. Hautant and Professor Lemaitre, vice president, and secretary, Dr. Tarneaud, 27, Avenue de la Grande Armée, Paris 16.——The International Society of Orthopedic Surgery will hold its second congress in London, July 19-22, 1933. The subjects chosen for consideration are "Mechanism of Articular Movements in General" and "Treatment of Tuberculosis of the Hip." Professor Nové-Josserand, Lyons, France, is president of the congress and Dr. Delchef, Brussels, Belgium, secretary.——The Surgical Society of Egypt was formed at a meeting, April 8, at the Faculty of Medicine, Kasr El Eini, Cairo, called by Prof. Aly Ibrahim Pasha, the dean. This action was prompted by the decision of the International Society of Surgery to hold its next congress in Cairo in 1935. A committee of nine surgeons was appointed to draft statutes for the new society and to represent Egyptian surgeons at the congress.

CORRECTION

Administration of Arsphenamine.—In Queries and Minor Notes, The Journal, June 11, page 2157, appears the statement that 0.85 cc. of tenth normal sodium hydroxide is to be used to each tenth of a gram of arsphenamine. Dr. C. H. McDougall of Washington, D. C., calls attention to the fact that this statement should read: 0.85 cc. of normal sodium hydroxide to every tenth gram of arsphenamine.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 13, 1932.

The Sterilization of Defectives

A conference on voluntary eugenic sterilization has been held by the Eugenics Society. Dr. R. L. Langdon-Down, an authority on mental deficiency, said that it was not easy to determine what proportion of defectives was due to heredity. But even if sterilization could reduce the incidence of defect to only a slight degree, that was sufficient reason for asking that the legal obstacles to voluntary sterilization be removed. Medical opinion was almost unanimous that certain cases of mental deficiency were preventable by this means and by no other. Sir Thomas Horder said that sterilization differed from birth control not in principle but only in efficiency. But in the present state of the law if the operation was performed on other grounds than in the interest of the patient's health, the surgeon would be in danger of an action for damages, notwithstanding that the full consent or even request of the patient was given. The danger would be all the greater if the operation was performed at the request of the patient's guardian.

Mrs. C. B. S. Hodson called attention to the experience of some American states in which sterilization of mental defectives had been carried out for about thirty years. There appeared to be a diminished tendency to promiscuity among those operated on, probably because of careful education in the institutions and supervision afterward. Miss Pocock stated that Alberta, Canada, was the only province in the British empire which had an act authorizing sterilization of the mentally defective. This came into force in 1928 and, by the end of 1931, 106 cases had been presented for sterilization and the operation had been approved in 101.

The British government has appointed a committee of members of the medical profession and others to examine and report on the information already available regarding the hereditary transmission and other causes of mental disorder and deficiency; to consider the value of sterilization as a preventive measure, having regard to its physical, psychologic and social effects, and to the experience in other countries of legislation permitting it; and to suggest what further inquiries might usefully be undertaken in this connection.

Bill to Increase the Liability of Drivers in Automobile Accidents

The appalling number of road accidents has produced a public outcry, but in spite of recent legislation the government has not been able to do much to reduce the evil. In the House of Lords, Lord Danesfort introduced a bill entitling persons injured on roads by automobiles to recover compensation when they have not themselves caused the accident, without having to prove (as at present) negligence or misconduct on the part of the drivers. He pointed out that more than half the deaths on the road caused by automobiles were those of pedestrians, and many of the victims were children. At present the dice were loaded against pedestrians getting damages, and though insurance companies often behaved generously in the more serious cases they fought in their own interests and raised every possible legal defense. If the pedestrian was killed, the important witness for enforcing the claim was not available, and if he was seriously injured his recollection was probably confused. The difficulty and expense of providing other witnesses had resulted in pedestrians being compelled to accept what compensation the insurance company cared to give. Even if he succeeded in proving negligence on the part of the driver, the pedestrian was then faced with the necessity of rebutting the defense of contributory negligence on his part. If he failed in this, his claim might be rejected entirely. To do justice between drivers and the injured, the defense of contributory negligence should be abolished. Instead of being safe, the highways had become the most dangerous places in the country —infinitely more dangerous than railways.

The lord chancellor said that it was difficult to offer any strong opposition to the bill. Inquiries showed that it would cause a considerable increase in the premiums charged by insurance companies for automobile policies. Another effect would be that unscrupulous litigants would press more claims of an excessive or unfounded nature. For the government, Earl Plymouth, parliamentary secretary to the ministry of transport, said that the bill left the automobile driver with only one line of defense—to prove that the accident was due to the injured party. In every European country except two, other lines of defense were allowed. While not unsympathetic to the bill, the government felt that it had gone too far, but it would not oppose it. The bill was read a second time by a majority of 22 to 8.

Investigation of Cancer of the Breast

Some important conclusions are contained in a report by Dr. A. P. Luff on a collective investigation of cancer of the breast, initiated by the British Medical Association. Physicians were requested to keep a record of all cases that came under their notice during the period of the year ended September, 1930. The object was to obtain precise information as to the previous history, evolution (especially of the first symptom) result of treatment and duration. Reports of 1,651 cases had been received. The following conclusions were drawn. 1. The liability to cancer of the breast is not increased by bearing a large number of children. 2. The proportion of cases is higher in nonparous married women and in single women. 3. A painless lump was the first symptom noticed by the patient in 79.5 per cent of the cases, a painful lump in 8.7, and pain alone in 5.1. 4. Preceding breast troubles (injury, mastitis, abscess, sore nipple and Paget's disease) do not appear to be factors of much importance. 5. Pain was completely absent in two thirds of the cases and was not severe in the great majority of the remainder. 6. Only 23.1 per cent gave a family history of cancer. 7. The complete operation gave much better results than the incomplete. 8. The medullary type was the worst form of the disease. 9. Under 50 years of age, scirrhus is the least common type; over 50, the most common type. 10. Prophylactic treatment with radium after operation exercises a beneficial effect, as shown by the higher survival rate and lower recurrence rate, as compared with patients who either had no prophylactic treatment or prophylactic treatment with x-rays. 11. Prophylactic treatment with x-rays after operation is useless.

An Inquiry into Mass Radiation

The controversy aroused by the decision of the National Radium Commission to withdraw the 4 Gm. radium bomb from use, as the results were not satisfactory, has been previously reported (The Journal, April 2, p. 1197). A conference has been held by leading members of the profession, including the presidents of the Royal Colleges of Physicians (Lord Dawson of Penn) and Surgeons (Lord Moynihan) and members of the commission. The conference unanimously arrived at the following conclusions. 1. The Radium Commission was right in discontinuing the use of the 4 Gm. bomb at the present juncture, though this decision is without prejudice to the question of the therapeutic value of 4 Gm. or even larger aggregations of radium. 2. A fully equipped radium institute is needed in London, where the more difficult and speculative problems connected with radium and ray therapy can be studied by the combined efforts of a trained staff. 3. An expert committee should be appointed, with the following references: (*a*) What is the scientific case for mass radiation by radium and what are its advantages and dangers? (*b*) What are the advantages and risks of massive surface irradiation by radium compared with that of radium needles and radon seeds? The expert committee has been appointed. It consists of two physicists (Lord Rayleigh and Prof. J. C. McLennan) and specialists in the radiotherapy of medicine, surgery and gynecology and in experimental irradiation.

The Need of Classical Training for Physicians

There is still considerable discussion in high medical and political circles on the subject of the need of requiring students of medicine to possess a knowledge of Latin and Greek. The bill presented to the senate by Dr. Armbruster, senator from the department of Aube, and endorsed by his colleague Debierre, senator from the department of Nord, who has since died, aroused great interest in the medical syndicates; for, demanding, as it does, for admission to the facultés de médecine, the possession of the type of baccalaureate degree that includes Greek and Latin studies, it would tend to limit the number of medical students, eliminating those who have had only a purely scientific training, and also many foreign students. The project would indirectly diminish the crowding of the facultés de médecine. The bill has been passed by the senate but not as yet by the chamber of deputies, in which a new majority, influenced by socialism, has no sympathy for classical culture and is inclined rather to open the way to higher education to the masses who have not as thorough an education and among whom Latin, especially, is regarded as associated with the conservation of the Roman Catholic faith. With the intention, no doubt, of exerting pressure on the sentiments of the new chamber of deputies, which will soon convene, many meetings have been held in favor of Greek and Latin studies as a necessary preparation for the study of medicine. One meeting, which was particularly important, was a public debate, held under the chairmanship of Professor Lépine, dean of the Faculté de médecine de Lyon, in the town-hall of the tenth arrondissement in Paris. Professor Rist, who was the first speaker, upheld the need of a knowledge of Latin, which was the forerunner of French, but Greek he would leave an optional study. Professor Sergent protested immediately, calling attention to the abundance of medical terms derived from Greek roots and emphasizing the great value of Greek roots in forming new medical terms, since a single compound word often takes the place of a long definition. In his opinion, if the physicians approved the suppression of the Greek, the politicians would not hesitate to follow with the abolition of the Latin. Mr. Armsbruster, Mr. Blum, professor at the university, and Dr. Cibrié, secretary of the Union des syndicats médicaux and a delegate of the Société corporative des étudiants en médecine, spoke along the same lines and demanded for the physician the highest intellectual culture possible, in order that he might contend against the moral weakening of the profession in the midst of the so-called realist spirit (but in reality a material and commercial spirit) of the present day. Shortly after this meeting, which appeared to influence public sentiment to a certain extent, the alumni association of the lycées of France and the colonies held its annual meeting at Rochelle. Its members are scattered today throughout many different professions. A similar debate was held, and the meeting pronounced unanimously in favor of making Latin and Greek compulsory requirements for admission to the study of medicine.

Surgical Shortening of the Sound Limb in Coxalgia

The Société des chirurgiens de Paris has heard, of late, many presentations of cases in which a surgical shortening of the sound limb in coxalgia, which operation appears to be coming into favor, was performed. In reality, the operation is not new. It was performed for the first time by Calvé of

Berck, who made a resection of the sound femur in a patient to bring the healthy leg up to the exact level of the leg shortened by coxalgia. The lameness is not totally suppressed, for the operation does not remedy the luxation of the hip; but the operation contributes considerably to the comfort of the patient, since he can walk afterward without an orthopedic device and can enjoy open-air life, which is so necessary for persons convalescing from tuberculosis of the bones. The operation was next performed by Dr. Raphaël Massart in France, and later by Hugo Camera at Turin, in 1931. Massart described to the society the technic of the procedure that he employs, and reported the excellent results that he secured from the operation. He sees only two objections to this form of intervention: the difficulty of inducing the patient to accept the operation, which reduces his height by from 5 to 6 cm., and the risk involved in any surgical operation that is not absolutely needed. Massart first assures himself, by means of careful roentgenologic examinations, of the absolute soundness of the bone that he plans to resect. Preliminary to the operation he disinfects scrupulously the skin of the adjoining area, and performs his resection so that the two bone fragments fit together exactly. A simple metal ring unites the fragments and the limb is placed in an extension apparatus for forty days. The results that he has secured were practically perfect. Mr. Marcel Galland, while approving the method of Calvé, emphasized the fact that absolute correction of the lameness cannot be attained by such an operation.

A New Conception of Mumps

The old conception, dating from Hippocrates, which considered mumps a local disorder—a parotiditis—with various later complications, is no longer tenable. It is evident that mumps is a general infection, which is known to be extremely contagious and which has as its causative agent a specific organism, concerning which, it is true, there is no common agreement. Mr. Philibert, associate professor at the Faculté de médecine de Paris, in an article published in the *Progrès médical,* holds that mumps infection is due to a cytotropic and neurotropic virus comparable to that of rabies. Having penetrated the organism by a route still undetermined (possibly the conjunctiva), this virus reaches, through a process of selection, the nerve centers, provoking in the meninges a more or less intense reaction. If but slightly virulent, it causes only slight and transitory lesions. If more active, it may bring about the destruction of nerve cells, and hence definitive paralysis, which is sometimes observed. From the nerve centers, it is eliminated by the salivary glands, of which it may or may not provoke a swelling and partial destruction; likewise by the pancreas, the testis and the kidneys. To sum up, mumps must be regarded today as a primary neuraxitis, accompanied by secondary lesions of the salivary glands, the pancreas and the testis.

Deaths

The death of Dr. Sherwood Dunn, at the age of 65, is announced. He was a member of the faculty of medicine of Paris and of the University of New York. He had previously served as an associate professor of the University of Boston. At Paris, he was elected a member of the Société de gynécologie et d'obstétrique. During the war, he served as the head of the American Red Cross unit at Amiens, holding the rank of colonel, and was severely wounded at Compiègne. He was awarded the title of Officer of the Legion of Honor. He was medical correspondent, in France, of several American journals. He resided, for the most part, at Nice, where he had founded the American Club.

The death of Mr. Pierre Breteau, as the result of an automobile accident, at the age of 50, is announced. He was a member of the Academy of Medicine, and was professor of chemistry and chief pharmacist at the Ecole militaire du Val-de-Grâce. He was the author of numerous works on the alkaloids, the hematins of the blood, oxydase reactions, and kindred topics.

The Swarm of Charlatans in Germany

According to an official survey contained in the *Reichsgesundheitsblatt,* the number of lay practitioners in the German *reich,* during the past two generations, was as follows:

Year	Totals	Females	Per 10,000 Inhabitants	For Each Ten Physicians
1876	670	95	0.16	0.49
1909........	4,468	1,322	0.70	1.46
1927........	11,761	2,832	1.86	2.70
1928........	12,098	2,803	1.90	2.63
1929........	12,413	3,091	1.94	2.61
1930........	12,942	3,094	2.01	2.74

In fact, there were more lay practitioners than these records show. This official report, however, deserves careful study, for it shows clearly the danger that threatens the health of the German people at the hands of charlatans. This report of the federal bureau of health reveals that the charlatans, that is, "unlicensed persons who treat patients as their regular occupation," show an increase of 4.3 per cent over the previous year, whereas the total number of persons engaged in the treatment and care of the sick increased only 0.3 per cent. If the defects and omissions of statistics are taken into consideration, it must be admitted that not nearly all wandering charlatans are included in the foregoing table. In the first place, there is a large number of quacks that failed to register with the police, as they are required to do. Furthermore, there is the immense army of pedlers with charlatanic tendencies, 700 of whom, according to court testimony, were employed by a single firm (the Fi-Sü G. m. b. H., Frankfort-on-Main), which was recently dissolved. Then there are the countless ranters and wandering healers belonging to the associations of charlatans, who, as is not so generally known, constantly lambast in their harangues all scientific medical research, deride the government's administration of medical affairs and, without stint, heap scandalous charges against the German physicians. In the foregoing official table the female lay practitioners are likewise estimated too low, since countless fortune tellers, astrologers and graphologists, who, as is well known, nearly all give medical advice and medical treatment, are not enumerated. Mention may be made also of the countless number of societies that, under the name of organizations or leagues for the care of public health or the promotion of a certain method of healing, carry on the treatment of their sick members as if a social game were involved. But even taking these incomplete statistics, there were, in 1930, in Germany 27.4 charlatans to every hundred physicians. From two other tables published in the *Reichsgesundheitsblatt,* it may be seen that in Saxony there were 1,759 charlatans as against 3,550 physicians (nearly 50 per cent); in Hamburg, 1,119 charlatans as against 1,523 physicians (73.5 per cent). No doubt the distress connected with the bad economic situation, during the past year, has induced more persons than ever to adopt the lucrative occupation of a charlatan, which requires no previous training, no factual knowledge and no material equipment. But the gravest danger does not lie in the increasing numbers of charlatans. The federal government, the legislatures and the general public would get a clearer idea of this menace if, not stopping with dry figures, exhaustive official reports of the disasters caused by charlatans could be published.

Answers to the following questions would be valuable: 1. What callings or occupations did the 12,942 charlatans abandon to take up the occupation of lay practitioners? 2. What is the average occupational training of the charlatans in Germany? 3. What diagnostic and therapeutic methods do they employ? As the health officers (the communal physicians, the district physicians and others) have in their possession the official list of registered charlatans, statistics on their antecedents would not be difficult to secure nor involve much expense. Such an official inquiry would seem to be worth while. Thus far the reichstag has failed utterly in its endeavors to curb the growth of charlatanry.

Progress in Supplying Aid to Tuberculous Patients

As evidence of progress in the supplying of aid to tuberculous patients, it may be mentioned that, according to the reports of the German care-taking centers for the tuberculous, for the fiscal year 1930, as published in the *Tuberkulose-Fürsorgeblatt*, more patients with active tuberculosis have a bed of their own than in previous years. Whereas, as recently as 1925, about 31 per cent of patients with active tuberculosis did not have a bed to themselves, the number has been constantly reduced in recent years, and in 1930 had dropped to 4 per cent. Of 111,000 patients with active tuberculosis, there were only 4,481 that did not have a bed to themselves.

New Method of Taking Roentgenograms of the Lungs

Professor Torelli communicated recently to the Federazione per la lotta contro la tubercolosi in Rome a new method for the taking of lateral roentgenograms of the pulmonary apexes. In the ordinary lateral roentgenogram, the upper third of the pulmonary field is invisible because covered by the shadow of the shoulder, whereas in the lateral roentgenogram taken by the Borson-Kappenstein method (axilla-shoulder) only the upper part of the apex is visible. With the Torelli method, the patient is placed with the side toward the roentgen apparatus, with the arm of the side to be examined held high above the head, while the shoulder of the opposite side is allowed to droop. The exposure results better if preceded by radioscopy. The cone of rays enters the shoulder of the opposite side, traverses the upper part of the mediastinum, the upper third of the side to be examined, and emerges from the axilla that rests on the apparatus. In the roentgenogram the field of investigation appears as a triangle, the sides of which are formed posteriorly by the shadow of the spine and below by the clavicle of the side to be examined. This exposure is especially valuable in bringing out the cavities of the upper third when the sagittal exposure is not sufficient to secure an accurate cavity diagnosis.

Center for Bibliographic Information

At the Biblioteca Vittorio Emanuele in Rome, the Centro nazionale di informazioni bibliografiche has been established, the object of which is to furnish to Italian and foreign students such information as will aid in their research and to point out the libraries in which they can find the publications and manuscripts that interest them. The organization will also function as an intermediary organization for the exchange of information of a bibliographic nature. The Italian libraries are under obligation to comply with the requests for information submitted to them by the newly established center.

New Sanatoriums

Under the auspices of the Cassa nazionale per le assicurazioni sociali, and for the purpose of promoting the crusade undertaken against tuberculosis, thirty new hospital-sanatoriums are in course of construction, which will have a bed capacity of 9,000. Plans for thirteen more sanatoriums to be located in various regions are being considered, and it is hoped that in 1934 the Consorzi provinciali antitubercolari (provincial antituberculosis societies) will have about 17,000 beds available in fifty hospital-sanatoriums, in addition to the patients enrolled in the village of Abetina di Sondalo, in Valtellina.

Italian Contributions at International Congress of Surgery

At the Congresso internazionale di chirurgia, held at Madrid last March, the Italian surgeons made notable contributions. Professor Lusena of Genoa collaborated on the subject of surgery of the esophagus, speaking on the traumatic lesions and their outcome, lacerations and wounds, traumatic paralysis, burns and cicatricial stenoses. He surveyed the pathology and the clinical aspects of the various types of diverticula, for which he considers the Mayo method the best form of treatment. In esophageal cancer, a resection is technically possible in any segment, but it is difficult to carry out and the percentage of recoveries is low.

Professor Ascoli of Rome presented a paper on "Tuberculous Pulmonary Suppurations." Among twenty-seven cases observed in the Clinica chirurgica at Rome, only one case was postoperative. For the differential diagnosis, the radiologic examination and bronchoscopic examinations are useful. Of the twenty-five patients, three made a spontaneous recovery; thirteen recovered after an operative intervention, and eleven died following the operation.

Professor Dominici of Perugia spoke on intraspinal tumors, reporting the statistics of sixty-three cases of spinal tumors that came to operation in Italy, and emphasized that good functional results were obtained only when the intervention was early; if possible, in the first, preparaplegic stage. In that stage, however, the diagnosis is difficult, owing to the varied nature and slight significance of the symptomatology. In doubtful cases the speaker favors exploratory laminectomy.

BELGIUM

May 18, 1932.

Social Insurance

The question of the advisability of enacting a social insurance law is interesting all medical circles and is much discussed at medical meetings. Opponents of such legislation are calling attention to the fact that a plebiscite in Switzerland has definitively condemned social insurance. The Academy of Medicine of Belgium has been studying the question. It has refused to take a stand on the economic and social need of social insurance, contending that it is not qualified to do so. But it considers it a duty urgently to call the attention of the government to the inevitable and profound repercussive effects that social insurance will have on the practice of medicine and pharmacy and on the welfare of patients, and likewise on the professional interests and possibly even on the morale of the medical and pharmaceutic professions. The academy has repeatedly emphasized that if the social insurance law is enacted, provisions must be made that will guarantee to physicians the free practice of their profession, preserve its liberal character in general and maintain intact the right of privileged communication, which is an actual public need. The academy has especially stressed the great importance of special legislative measures that will protect the clinical instruction at the universities. Such instruction would, it contends, be menaced by the creation of hospitals, clinics and other therapeutic institutions that would not be recognized as indispensable.

Enameling and Lead Poisoning

Addressing the Société de médecine et de chirurgie du travail, Mr. Glibert, president of the Comité technique representing the interests of victims of occupational diseases, called attention to the fact that certain enameling processes are exceptionally harmful because the enamels contain lead, since the morbidity is sixty times that of the general average of the industries that expose workmen to lead poisoning. According to the writer, the suppression of the use of lead-containing enamels is feasible and should be done.

Organization for the Promotion of "Social Prophylaxis"

The executive committee of the Fédération médicale belge has decided to create an organization for the promotion of "social prophylaxis." Physicians attached in any capacity to an organization of social medicine are invited to cooperate. It is a question of the forming, under the egis of the Fédération médicale belge, of a section for the study of social medicine, the principal object of which will be to coordinate the efforts of the organizations mentioned with a view to establishing a better prophylaxis of public health. The first questions studied will be (1) the right of privileged communication in relation to social medicine (certificates, inquiries), (2) the collaboration of medical practitioners with medical consultants, and (3) relations between consultants and practitioners from the point of view of treatment.

Cerebrospinal Meningitis in Camps of the Union Minière

In the medical bulletin of Katanga, Dr. Van Nitsen gives an account of the epidemic of cerebrospinal meningitis in the camps of the Union Minière during the period 1925-1930. Cerebrospinal meningitis, which is endemic in Katanga, manifests itself usually in sporadic cases. In 1925 there arose in the camps of the Union Minière a severe epidemic, which lasted through 1926, 1927, 1928 and 1929. In 1930, only rare sporadic cases were noted. The measures adopted to combat the epidemic consisted in preventive vaccination by means of a vaccine prepared from local strains, and hygienic measures looking chiefly toward an improvement in the dwellings of the native workers. These measures had a favorable effect on the epidemic, but it is difficult to say which one exerted the chief influence. The author believes that the results obtained should be attributed to the hygienic measures rather than to the vaccination.

Death of Dr. Heymans

The death of Jean François Heymans, emeritus professor at the University of Ghent, is announced. In Professor Heymans one of the beautiful figures known throughout the extent of international science has passed from the scene of action. His professional career began at Ghent in 1890, and in 1896 he accepted the chair of therapeutics and pharmacodynamics. Professor Heymans founded, thirty-six years ago, in collaboration with Professor Gley, the *Archives internationales de pharmacodynamie et de thérapie.*

The New School Ship

The *Bruxelles médical* publishes an interesting description of the new school ship, designed to replace the *Avenir.* The new ship bears the name *Mercator,* in memory of the eminent Belgian who invented the hydrographic or marine map. This school ship, the plans for which were drawn by Baron de Gerlache, includes a medical department and hygienic improvements that deserve special mention. The spacious hospital quarters are amidships, which assures to patients the maximum of stability. That is one of the desiderata recommended by the Maritime Conference of Geneva and by the Congress of the International Association of Officers of the Merchant Marine. The medical rooms, which are large, well lighted and well ventilated, include a consultation room, an operating room, an infirmary, bathrooms, and a pharmacy. An isolation ward with hygienic equipment is located in the center of the upper deck. All the medical equipment is of Belgian manufacture. Special provision is made for taking on board large supplies of drinking water, which may be three times the minimum required. All the floors will be covered with linoleum, kept clean by a special mopping process. The ancient deplorable custom of flushing the interior of the ship with the hose, a system condemned by all hygienists but which it is so difficult to uproot from a milieu in which the influence of tradition is often paramount, will thus disappear. The bedding will be stowed, during the day, in a special place under the bulwarks, where it can be properly aired and sunned. Shower baths have been provided.

The Association of Clinics

Under the auspices of the Fédération médicale belge, an association of the medical directors or mandataries of clinics and policlinics has been created. The purposes of the association are to (1) strengthen the ties between medical directors or mandataries of the various clinics and policlinics of medicine, surgery and the specialties; (2) apply the adaptation of the rules of deontology and of confraternization to the administration of clinics and policlinics; (3) combat the illegal practice of the art of healing and charlatanism; (4) supply members with literature deemed valuable and useful, and (5) supply the public and the insurance organizations, mutual aid societies, administrations and other groups with a complete list of medical institutions. The researches of the association will have as their chief objectives (1) establishing of ties of solidarity between its members with a view to promoting harmony between the various organizations; (2) adoption of minimum tariff schedules in accord with the Fédération médicale belge, and taking account of the regional needs, and (3) study of the questions that are submitted to it by the executive committee of the Fédération médicale belge.

AUSTRALIA

(From Our Regular Correspondent)

May 16, 1932.

The Third Australian Cancer Conference

At the third Australian Cancer Conference, many facts were brought out. The facilities for the treatment of cancer in Australia have been expanded during 1931 in respect both of accommodation for patients and of additional apparatus for treatment. The use of radon has been extended during the past year. It is now being prepared in Melbourne, Sydney and Adelaide, the year's output being 17,021, 2,040 and 4,200 millicuries, respectively, for each center. This represents an increase of 43 per cent over 1930.

CANCER STATISTICS

In the last three and a half years, to Dec. 31, 1931, more than 9,000 persons have received treatment with radium at the several treatment centers for various malignant and other conditions. The exact number is not known, owing to failure on the part of some of the treatment centers to supply their figures. Of 3,031 patients treated for carcinoma (excluding rodent ulcer) in all stages of the disease in the three years ended June 30, 1931, 2,000, or 36 per cent, are alive and free of symptoms: 22 per cent are known to have died of cancer. Of 1,265 patients with carcinoma classed as operable, 54 per cent are alive and free of symptoms. Only 4 per cent are known to have died of cancer, but in 22 per cent information as to the subsequent history of the patient is not available.

Although the year 1930 showed a decline in the cancer mortality rate for the commonwealth per hundred thousand of mean population, of the total deaths from all causes the proportion that was due to cancer still continued to rise. Thus, among males, one death in every 9.8 and among females one death in every 8.1 was caused by cancer in 1930, this proportion being the highest yet registered in the commonwealth. Neglecting the population under the age of 40 years, in which death from carcinoma seldom occurred, the mortality statistics showed that in males dying after the age of 40 one death in every eight was due to cancer and in females one death in every six. The steady rise in the cancer mortality rate, which was apparent for many years, mainly appears in carcinoma of various organs. The mortality rate from sarcoma is now practically at the same figure that was recorded twenty years ago and has shown relatively little fluctuation in the interval.

As regards regional cancer, mortality from cancer of the tongue in males showed a definite decrease. The rate per hundred thousand of mean population in 1908 was 3.9; in 1930 it was 2.7. Whereas in 1908 one death in every seventeen deaths from cancer was due to carcinoma of the tongue, the proportion in 1930 was one in thirty-five. In females (among whom cancer of the tongue was relatively rare) there was no corresponding diminution in mortality rate, but rather an increase. In no region except that of the tongue did a diminishing mortality rate for cancer appear. In respect of some regions, however, the mortality rate increased much more rapidly than in others. Thus in females the mortality rate from carcinoma of the breast increased at a much faster rate than that for carcinoma of the female genital organs. The region in which the most rapid increase in the mortality rate from cancer occurred was the digestive tract (esophagus to rectum). Here the increase since 1908 was approximately 100 per cent in males and 80 per cent in females. In males, 1 death in every 1.9 deaths from cancer was attributable to cancer of the digestive tract. In females the proportion was 1 in 2.6. In cancer of the skin the mortality rate, which until 1918 steadily rose, has shown since that date a distinct though fluctuating tendency to fall. In 1918 the mortality rate from cancer of the skin was 5 per hundred thousand of mean population. The rate for 1930 was 4 per hundred thousand. The records of cancer treatment centers were kept on uniform lines, enabling the statistical material to be consolidated. The period covered by these returns was only three years, and this period is not long enough to enable detailed conclusions to be drawn as to end-results of treatment. One or two wide facts of interest can, however, be indicated. In a period covering approximately three years to Dec. 31, 1931, the total number of patients treated by means of radium or radium combined with some other method by treatment centers associated with the national organization for the control of cancer in Australia was 9,431. Of these, 4,025 were treated for carcinoma, 3,011 for rodent ulcer, 247 for sarcoma, and 271 for conditions such as endothelioma, melanoma, teratoma and conditions of doubtful malignancy. The remainder suffered from benign tumors or other nonmalignant conditions.

These figures do not include any cases of cancer in the treatment of which radium was not used. Of 3,031 patients with carcinoma treated by means of radium or radium combined with some other method up to June 30, 1931, 36 per cent were alive and free of symptoms at the end of 1931, 22 per cent were known to have died of cancer, and in 17 per cent of cases information as to the end-result was not available. Of 1,265 patients with operable carcinoma, 54 per cent were alive and free of symptoms, 4 per cent were known to have died of cancer, but in 23 per cent of cases the end-result had not been ascertained.

In regard to sarcoma, 45 per cent of the patients with operable and borderline conditions treated during the three years up to the end of June, 1931, were alive and free of symptoms at the end of 1931, whereas, of those with inoperable conditions, 17 per cent remained alive and free of symptoms.

Results of treatment by means of radium and radium combined with other methods were good in the case of cancer of the skin and of the lips and in operable tumors of the buccal cavity, uterus and breast. In a large proportion of cases, however, varying from 29 per cent of patients suffering from cancer of the skin and 30 per cent of those with rodent ulcer to 7 per cent of patients suffering from cancer of the buccal cavity, the end-results of treatment had not yet been ascertained. The information that is being gathered is becoming more accurate, and with greater application in ascertaining the end-results of treatment and with the increasing length of the period elapsing since treatment was given, records will be available of the greatest value in enabling deductions to be drawn as to the true value of the various methods of treatment in cancer of different regions.

CANCER RESEARCH

The most important research work has been carried out at the University of Sydney. There Dr. Warnford Moppett has been investigating the relation between the effects of x-rays on various tissues, including clinical material, and the reaction obtained by him when the chorio-allantoic membrane of the chick embryo is exposed to homogeneous radiations. Experiments carried out illustrate the extraordinary potency of homogeneous radiation. To facilitate the measurement of doses of x-rays, Dr. Moppett constructed a thermo-electrical instrument to record the rise of temperature when radiation is totally absorbed by a bismuth plate. With this instrument the Solomon and international units of x-ray doses have been evaluated in ergs, and variations of x-ray energy dependent on changes of potential and milliamperage have been investigated. Dr. Moppett and Dr. Harker have carried out experiments with sodium iodo-acetate on tumor-bearing mice. They have repeated the experiments of Lundsgaard, who showed that iodo-acetic acid in low concentration, while having little effect on the oxidative metabolism of carbohydrates, exercises a powerful inhibitive effect on the fermentative or glycolytic metabolism. Dr. Moppett and Dr. Harker have given the iodo-acetate orally instead of by injection. They have found that no iodo-acetate is absorbed by the tumors.

Need for an Improved Classification

During the period 1908 to 1923, of 63,148 deaths from cancer in Australia, 26.65 per cent were certified as due to "cancer" without further qualification, 11.74 per cent were certified merely as due to malignant disease, 1.50 per cent as due to malignant tumor, and 0.47 per cent as due to neoplasm. A total of 40 per cent was certified so indefinitely that it was not even known whether the death was from such widely different conditions as carcinoma or sarcoma, except as indicated by the site, and even this was not always indicated. The position is better today but is still bad. What is necessary and has not yet been provided is a uniform pathologic classification for the use of certifying medical officers in the certification of deaths from cancer. This is essential to the proper investigation of cancer.

The international nomenclature of causes of death as amended in 1929 is not satisfactory as regards the classification of cancer. It is realized that a biopsy is almost essential in making a correct certification, and that in many cases, especially in private practice, this is not possible and in certain types of growth is not desirable. It is also realized that a too intricate classification will only cause confusion. It was resolved to appoint a subcommittee to study the whole question.

NOTIFICATION OF CANCER

The question of the desirability or otherwise of making cancer a notifiable disease was discussed at a previous cancer conference, but there had been some divergence of opinion among members. It was decided that steps should be taken to ascertain from the members of the profession throughout the states whether or not the time has arrived to make cancer a notifiable disease. Communications were sent accordingly to the several branches of the British Medical Association asking for the views of the members of each branch on the matter of the notification of cancer. The Queensland, New South Wales, Victorian and South Australian branches were not in favor of notification. The Western Australian branch thought that it was desirable to make cancer a notifiable disease by means of some form of confidential report. No reply was received from the Tasmanian branch.

INFLUENCE OF CONTRACEPTIVES ON THE DEVELOPMENT OF UTERINE CANCER

The influence of contraceptives on the development of uterine cancer had been considered at a previous conference but had been held over pending further investigation. The feeling of this conference was that there was no statistical evidence at present to support such a relationship and that complete statistics were difficult to obtain. In any case, the possible influence was slight compared with that of cervical trauma in parturition and abortion, and cervical infections in the causation of malignant cervical neoplasms. Statistics indicated that the great majority of cases of cervical cancer occurred in married women who had borne children or who, on account probably of some morbid condition of the uterine mucosa, were sterile.

PROTECTIVE MEASURES IN CONNECTION WITH THE USE OF X-RAYS AND RADIUM

The revised international recommendations, as laid down by the third International Congress of Radiology (Paris, July, 1931) had been circularized to all treatment centers. The Australian outlook was that two factors had to be considered: (*a*) the measurement of the radiation intensities and (*b*) the tolerance intensity to which a worker could safely be exposed. It was considered that the best method of measuring the intensity was by the photographic method, and that a fair estimate of the tolerance intensity was 4×10^{-4} r/minutes. Thus in one year of 300 working days a dose of approximately 60 r would be received. As a further precaution, the conference urged the importance of a quarterly exchange of the nursing staff associated with roentgenologic clinics.

Based on the recommendation of the international protection committee that, for voltages of 400 kilovolts peak a thickness of 1.5 cm. of lead or its equivalent should be provided, the walls of a new block that is being built at St. Vincent's Hospital, Melbourne, are being built of barium cement. It has been found by test that a thickness of 10 cm. of such brick is equivalent in protective power to 1.9 cm. of lead. The bricks were made of two parts of coarse barium sulphate, one part of barium flour and one part of portland cement. They were tongued and grooved to prevent joint leakage, and the lead sheeting on the ceiling and sliding doors overlapped the bricks.

TURKEY

(From Our Regular Correspondent)

Ankara, May 16, 1932.

History of the Turkish Red Crescent Society

The conference at Geneva, held Aug. 8, 1864, to which the governments of sixteen countries sent delegates, decided on the basic principles of Red Cross organization. The Geneva convention was signed, Aug. 22, 1864. Twelve months was allowed the various governments for declaring their adherence to the convention. Turkey signed the international agreement, July 5, 1865. The honor of taking the first step toward founding the Red Crescent Society in Turkey belongs to Dr. Abdullah Bey (Hammerschmidt), of German origin, who had spent years in the army medical corps and who attended the sanitary conference in Paris in 1867 as delegate of the Ottoman Empire. On his return, Dr. Abdullah Bey proceeded to the organization of a committee. Numerous were the obstacles. He called on his confrères to form a committee. Only sixty-six persons responded to the call, forty-three of whom were physicians. In July, 1869, the constitution and by-laws of the society were formulated and unanimously adopted by the committee, but the Sublime Porte did not approve of the society under the pretext that the ministry of war regarded it as an encroachment on military affairs. Shortly afterward the second Red Cross conference met in Berlin. The Ottoman Empire was represented by Aristarki Bey, the Turkish ambassador at Berlin, and Husni Bey, military attaché at the Turkish embassy in Paris. Seven years later the Montenegro, Serbian-Turkish war broke out, followed by the war provoked by Russia and Rumania. The reports of the activities the Red Cross societies of neutral countries displayed on the battlefields among the wounded Serbs, Montenegrans, Russians and Rumanians, while the Turkish army was encountering the greatest difficulties in connection with the care of her wounded, at last shook off the indifference which the Sublime Porte had hitherto shown. More than ten years had elapsed since the Sublime Porte had signed the international agreement, but the commanders of the Turkish armies did not even know the purpose and the aims of the Geneva convention. Then Gustave Meunier, president of the international committee of the Geneva convention, wrote to Dr. Peshtemalgian. The contents of this letter were submitted to the imperial medical society, which sent a delegation to Mehmed Rushdi Pasha, the grand vizier. Within a week, a committee was formed at the imperial medical school, where the first meeting took place, July 31, 1876, under the presidency of Marco Pasha, the director of the school.

The question of replacing the "cross" by another suitable emblem was discussed, with the result that the constitution and by-laws of the society were laid down, the organization of a subscription drive was decided on, the members of the administrative council were elected, and a delegation was sent to the war minister. The Sublime Porte asked but one reservation, that the "cross" be replaced by the "crescent" for the Turkish society. The request of the Sublime Porte having been accepted, the war minister approved the society's constitution, and on April 14, 1877, the Ottoman Red Crescent Society was founded. Sultan Abdul Hamid II opened the first session at the Beshiktash palace, thirteen years after the Geneva convention had been signed. The society had been founded on the eve of the Turkish-Russian war (1877-1878) and the armies in Rumania and Anatolia had to be provided with medical supplies. An appeal was made to the public for funds, to the Mohammedans of India and North Africa, and 72,583 pounds Turkish (gold) was realized. When war was over, the sultan, under the pretext that there was no reason for the further existence of the society, ended its activities by depositing the remaining 11,496 pounds at the Ottoman bank. Thus for the second time the society ceased to exist. It was not until 1897, almost twenty years later, that for a short time on the occasion of the Turkish-Greek war the society came back to life. The original founders set to work again. Two hospital ships for the transport of wounded soldiers were equipped and the army was furnished with medical supplies. The minister of finance petitioned the grand vizierate, asking the nomination of a president and additional members with the object of bringing to life the society's activities, but the sultan refused and the end of the Turkish-Greek war was also the end again of the Red Crescent Society. No further activities were possible until the proclamation of the constitution in 1908. In April, 1911, the society was reorganized and placed under the patronage of Sultan Reshad V. The crown prince was chosen honorary president and the society resumed its activities under the name of "Central Committee of the Ottoman Red Crescent," Rifat Pasha, minister of foreign affairs, the president, and twenty-nine members forming the central committee.

It is only since the refounding in 1911 that the Red Crescent Society has had the opportunity to organize its activities unhampered. It has since come to the relief of those in distress in all kinds of local calamities and has been active in meeting part of the needs arising through the Tripoli war of 1911, the Balkan war of 1912, the World War, 1914-1918, and the War of Independence, 1919-1922. When by decision of the great national assembly the Ottoman Empire ceased to exist in 1923, the society's name was changed to "Turkish Red Crescent Society" and in 1925 its headquarters were transferred to Ankara, the capital of the republic.

Marriages

Harold Benjamin Smith, North Wilkesboro, N. C., to Miss Mary McLeod, Cheraw, S. C., June 10.

Clarence Loveridge Robbins to Dr. Marion B. Leonard, both of New Haven, Conn., June 25.

Henry Rostler Bloom, Boston, to Miss Ruth Naomi Elkins of Chelsea, Mass., June 26.

Harry Rosenwasser, New York, to Miss Mildred Boley of Athens, Ga., recently.

Clarence W. Rainey to Dr. Clarissa E. Devney, both of Chicago, April 30.

Charles E. Hall, Jr., to Miss Virginia Manston, both of Atlanta, Ga., June 20.

Edward Berkeley Neal, Douglas, Ga., to Miss Ethel Dickerson, May 28.

Glenn R. Walker, Mobeetie, Texas, to Miss Elise Stiles in Calvert, May 5.

Joseph Cullen Root, Akron, Ohio, to Miss Mary Heppberder, April 28.

Deaths

William Tod Helmuth, New York; New York Homeopathic Medical College and Hospital, 1887; emeritus professor of surgery at his alma mater; fellow of the American College of Surgeons; formerly consulting surgeon to the Flower Hospital and the Broad Street Hospital, New York, New York State Hospital for Crippled and Deformed Children, West Haverstraw, Middletown State Homeopathic Hospital, Middletown, Yonkers (N. Y.) Homeopathic and Maternity Hospital, Jamaica (N. Y.) Hospital, Essex County Hospital, Cedar Grove, N. J., White Plains (N. Y.) Hospital, and St. Mary's Hospital, Passaic, N. J.; aged 69; died, June 15, at his summer home in East Hampton, of nephritis and arteriosclerosis.

Eugene Anthony Crockett ⊕ Boston; Harvard University Medical School, Boston, 1891; formerly professor of otology at his alma mater; member of the American Laryngological, Rhinological and Otological Society, the American Otological Society, and the New England Otological and Laryngological Society; fellow of the American College of Surgeons; served during the World War; on the staffs of the Massachusetts Charitable Eye and Ear Infirmary and the Peter Bent Brigham Hospital; aged 64; died, June 13, in Ipswich, Mass.

Edward Evans, La Crosse, Wis.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1887; member and past president of the State Medical Society of Wisconsin; member of the Western Surgical Association and fellow of the American College of Surgeons; served with the American Red Cross during the World War; formerly member of the board of education, and chairman of the city board of health; regent of the University of Wisconsin, 1902-1914; aged 72; for many years on the staff of St. Francis Hospital, where he died, June 1, of bronchopneumonia, thrombosis and arteriosclerosis.

Charles Rollins Grandy ⊕ Norfolk, Va.; University of Virginia Department of Medicine, Charlottesville, 1892; past president of the Medical Society of Virginia and the Norfolk County Medical Society; at one time member of the state board of health; formerly member and chairman of the school board; aged 61; died, June 10, of heart disease.

Amos Jay Hostetler, Lagrange, Ind.; Medical College of Indiana, Indianapolis, 1893; member of the Indiana State Medical Association; past president of the state board of health; member of the school board; formerly proprietor of a hospital bearing his name; aged 65; died, June 12, of progressive muscular atrophy.

Harrie Delmar Handy ⊕ Harwich, Mass.; Hahnemann Medical College and Hospital of Philadelphia, 1893; on the staff of the Cape Cod Hospital, Hyannis; aged 63; died, May 16, in the Massachusetts Memorial Hospitals, Boston, following an operation for vesical calculus, diabetes mellitus and chronic nephritis.

William Broaddus Pritchard, Princess Anne, Md.; College of Physicians and Surgeons, Baltimore, 1884; formerly professor of neurology at the New York Polyclinic Medical School and Hospital, New York; aged 69; died suddenly, June 6, of chronic nephritis and chronic valvular heart disease.

Bascom Franklin Morris ⊕ Tucson, Ariz.; Vanderbilt University School of Medicine, Nashville, Tenn., 1910; fellow of the American College of Surgeons; served during the World War; on the staffs of the Southern Methodist Hospital and St. Mary's Hospital; aged 43; died, June 7, of pneumonia.

Edward Carlin Bennett, Brooklyn; College of Physicians and Surgeons in the City of New York, 1886; member of the Medical Society of the State of New York; formerly on the staffs of the Norwegian Hospital and the Victory Memorial Hospital; aged 68; died, June 5, of heart disease.

Frost Craft Buchtel, Denver; Denver College of Medicine, 1901; member of the Colorado State Medical Society; formerly assistant professor of surgery, University of Colorado School of Medicine; on the staff of St. Luke's Hospital; aged 56; died, May 29, of heart disease.

Henry Blodget ⊕ Bridgeport, Conn.; Bellevue Hospital Medical College, New York, 1881; for many years on the staffs of St. Vincent's and the Bridgeport hospitals; aged 76; died, May 23, of coronary thrombosis, chronic endocarditis and myocarditis.

Joseph Edgar Cook, Cleveland; University of Wooster Medical Department, Cleveland, 1881; member of the Ohio State Medical Association; aged 76; died, May 31, in the Windsor Hospital, of cerebral arteriosclerosis and cerebral hemorrhage.

Jesse B. Munn, Vilonia, Ark.; University of Arkansas School of Medicine, Little Rock, 1899; member of the Arkansas Medical Society; for almost forty years member of the school board of Vilonia; aged 78; died, May 5, of mitral stenosis.

George Foster Comstock ⊕ Saratoga Springs, N. Y.; College of Physicians and Surgeons in the City of New York, 1883; fellow of the American College of Surgeons; surgeon to the Saratoga Hospital; aged 71; died, June 1, of heart disease.

Moses B. Harutun ⊕ Joplin, Mo.; New York University Medical College, 1896; for twelve years commissioner of health and sanitation; aged 65; died, May 19, in a hospital at St. Louis, following an operation for removal of the gallbladder.

Thad Cothern, Jonesboro, Ark.; Memphis (Tenn.) Hospital Medical College, 1905; member and past president of the Arkansas Medical Society; served during the World War; on the staff of St. Bernard's Hospital; aged 51; died, May 17.

Stonewall Jackson Gay, Lineville, Ala.; Southern Medical College, Atlanta, Ga., 1888; member of the Medical Association of the State of Alabama; formerly judge of probate of Clay County; aged 69; died, May 23, of heart disease.

Chambers B. Clapp, Moberly, Mo.; Rush Medical College, Chicago, 1889; formerly member of the school board; for fifteen years president of the Woodland Hospital; aged 73; died, June 12, in a hospital at West Palm Beach, Fla.

John Augustus Leas, Los Angeles; Indiana University School of Medicine, Indianapolis, 1908; member of the California Medical Association; served during the World War; aged 47; died, May 26, of cerebral hemorrhage.

Charles Augustus Leale ⊕ New York; Bellevue Hospital Medical College, New York, 1865; Civil War veteran; first physician to reach President Lincoln when he was assassinated; aged 90; died, June 13, of arteriosclerosis.

Edward J. Brougham ⊕ Chicago; Chicago Medical College, 1887; fellow of the American College of Surgeons; aged 66; on the staff of the Henrotin Hospital, where he died, June 15, of carcinoma of the tongue.

Henry Fleetwood Hoover, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1898; member of the South Carolina Medical Association; aged 56; died, June 4, in the Columbia Hospital.

Omar Hollinger Shively, Campbellsville, Ky.; University of Louisville School of Medicine, 1893; member of the Kentucky State Medical Association; aged 60; died, May 28, of myocarditis and coronary occlusion.

Charles E. Neal, Cincinnati; University of Cincinnati College of Medicine, 1913; member of the Ohio State Medical Association; aged 63; died, May 26, of coronary thrombosis and arteriosclerotic heart disease.

Edward M. Boggess, Elwood, Ind.; Medical College of Ohio, Cincinnati, 1887; member of the city board of health; for eight years coroner of Fayette County, Ohio; aged 69; died, May 31, of carcinoma.

George Conderman, Hornell, N. Y.; University of Vermont College of Medicine, Burlington, 1889; formerly mayor of Hornell; aged 63; died, June 11, in a local hospital, of pneumonia.

Francis Edward Lister ⊕ Faith, S. D.; Medical College of Indiana, Indianapolis, 1892; aged 65; died, May 30, in the Black Hills Methodist Hospital, Rapid City, of peritonitis and shock following an operation for ruptured gallbladder.

Charles Benjamin Bomberger, Mapleton, Minn.; University of Minnesota Medical School, Minneapolis, 1925; aged 32; died, June 7, in Colorado Springs, Colo., of pulmonary tuberculosis.

Eva Elizabeth McKnight ⊕ Oswego, N. Y.; University of Michigan Medical School, Ann Arbor, 1890; obstetrician to the Oswego Hospital; aged 73; died, June 10, of angina pectoris.

Henry Raymond Casgrain, Windsor, Ont., Canada; Faculty of Medicine of Trinity College, Toronto, 1883; served during the World War; aged 74; died, June 16, of heart disease.

Frederick O. Jackman, Bloomington, Ill.; Chicago Medical College, 1887; aged 73; died suddenly, May 30, at his summer home at Bass Lake, Ind., of cerebral hemorrhage.

Daniel Cessna De Walt ⊕ Houston, Texas; Baylor University College of Medicine, Dallas, 1909; served during the World War; aged 43; died, May 19, in a local hospital.

William Webster Sadler, Hershey, Neb.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902; aged 57; died, April 17, of chronic interstitial nephritis.

George Porter Emmons, Lewiston, Maine; Medical School of Maine, Portland, 1885; aged 72; on the staff of the Central Maine General Hospital, where he died, March 27.

Willard Thomas Conley, Dresden, Ohio; Medical College of Ohio, Cincinnati, 1887; aged 70; died, June 11, in the Mount Carmel Hospital, Columbus, of heart disease.

Ira Otis Tracy ⊕ Brooklyn; College of Physicians and Surgeons in the City of New York, 1882; aged 73; died, June 4, at Essex Fells, N. J., of carcinoma.

Charles Walker Mangus, Homestead, Fla.; St. Louis College of Physicians and Surgeons, 1891; aged 72; died, May 17, in Miami Beach, of pernicious anemia.

Walter Clay Sturm, Los Angeles; University Medical College of Kansas City, Mo., 1907; aged 52; died, April 2, of chronic myocarditis and coronary sclerosis.

Daniel Miller Sanger, New Lebanon, Ohio; Long Island College Hospital, Brooklyn, 1882; aged 87; died, May 6, of cerebral hemorrhage and arteriosclerosis.

Albert C. Clark, Woonsocket, S. D.; Chicago Homeopathic Medical College, 1895; aged 62; died, April 26, following an operation for gallbladder trouble.

Calvin W. Bufkin, Runnells, Iowa; Medical Department of Drake University, Des Moines, 1898; aged 60; was accidentally killed, June 11, while hunting.

Frank Summers Thomson ⊕ Dayton, Ohio; University of Louisville (Ky.) School of Medicine, 1888; aged 64; died, May 22, of carcinoma of the lower lip.

Francis Wallace Bruce, Carthage, N. Y.; Medical Department of the University of the City of New York, 1882; aged 78; died, May 16, of heart disease.

M. Jackson Anderson, Tampa, Fla.; Meharry Medical College, Nashville, Tenn., 1897; aged 70; died, May 7, of a ruptured appendix and carbuncle.

Thomas H. Bedford, Meshack, Ky.; Hospital College of Medicine, Louisville, 1875; aged 86; died, April 1, in Tompkinsville, of chronic myocarditis.

Paul Traub ⊕ Trenton, N. J.; Medico-Chirurgical College of Philadelphia, 1899; aged 58; died, June 9, at his home in Beach Haven, of heart disease.

Pierre Anselme Rontey, Coscob, Conn.; University and Bellevue Hospital Medical College, 1909; aged 48; died suddenly, May 13, of heart disease.

William Johnstone Latta ⊕ Wagon Mound, N. M.; Chicago Medical College, 1881; aged 75; died, June 4, in the Valmora (N. M.) Sanatorium.

Elmer A. Blessing, Albany, N. Y.; University of Vermont College of [illegible] 1885; aged 70; died, May 19, of carcinoma of the liver.

Albert P. Minshall, Viroqua, Wis.; College of Physicians and Surgeons, Keokuk, Iowa, 1890; aged 70; hanged himself, May 17.

Edward B. Felter ⊕ Plymouth, Wis.; Rush Medical College, Chicago, 1891; aged 67; died, June 8, of pneumonia.

Nicholas John Hamilton, Moline, Ill.; Chicago Physio-Medical Institute, 1886; aged 80; died, May 4, of heart disease.

Correspondence

"CESAREAN UTERINE SUTURES"

To the Editor:—The case report by Dr. Harry S. Fist in The Journal, May 7, page 1635, entitled "Cesarean Uterine Sutures Passed from the Vagina" records an interesting observation but one that bears critical interpretation. Although the patient had a low-grade temperature from 100.6 to 100.8 F. from the second to the seventh day, during which time the lochia were normal, she passed a mass containing the uterine sutures on the eleventh day. This was a necrotic slough. One would like to know how the wound edges were handled before the sutures were placed, whether hemostats or other crushing instruments were used on the uterine incision to control bleeding or to hold the edges in position for suturing.

The indictment of the continuous suture made by the author is not warranted by his single case, as many obstetricians have used continuous sutures with success. I have used continuous sutures consistently for the past five years and have never encountered this complication. Continuous sutures too close or tied too tightly may be a factor in lowering tissue resistance. In regard to Dr. Fist's comment on the integrity of the scar in future pregnancy, I believe that his reasoning is faulty. A wound that heals by secondary intention or granulation results in a *weak scar,* one that is likely to rutpure during subsequent pregnancy or labor. I feel that his patient would entail a serious risk of this accident were she allowed to become pregnant again.

Irving F. Stein, M.D., Chicago.

To the Editor:—I can report a case similar to that observed by Dr. Fist, in which the three undisturbed layers of continuous sutures used to close the uterus were passed in the lochia on the tenth day. The patient made an uneventful recovery, showing no abnormality on examination at six weeks. I do not know whether she had later pregnancies.

The method of handling wound edges makes little difference. It has been a common practice for years, at the Chicago Lying-In Hospital, to compress completely the line of incision in the lower uterine segment by means of modified stomach clamps, to render the operative field bloodless. This I have done many times without regret. Now, however, I first incise the entire length in the lower uterine segment even in the presence of placenta praevia cesarea without first clamping. After delivery of the baby I compress both edges from top to bottom with closely approximated tongue forceps, to close all sinuses and also hold the edges in position for suturing. Never have I seen such temporary pressure in this vascular area affect wound healing.

The use of the continuous suture for years without evident bad results does not justify the assumption that other methods are not better. Many conservative surgeons the world over are discontinuing the locked continuous suture in favor of loosely tied interrupted sutures. I have observed this tendency in numerous operators at the County Hospital in Chicago and elsewhere, showing that others appreciate the dangers of ischemia produced by the continuous suture. For primary union, nature requires merely good approximation of clean edges, without disturbance of circulation.

A weak scar will result if a wound heals by secondary intention; however, world reports show that such a scar in the lower uterine segment entails no greater risk than one in the anterior abdominal wall. Indeed, under certain conditions, spontaneous labor and delivery may be permitted, preferably assisted by episiotomy and early forceps.

D. A. Horner, M.D., Chicago.

[Note.—The letters were referred to Dr. Fist, who writes:]

To the Editor:—1. Wound edges were not traumatized by hemostats or other crushing instruments. The upper and lower ends of the intended incision were delimited and the uterus was steadied by means of two catgut traction sutures, as advised by DeLee and Beck. Thumb forceps were applied gently.

2. Your correspondent makes no indictment of the continuous suture but is now willing to agree with outstanding obstetricians (DeLee, Vaux, Beck) who feel that interrupted sutures are preferable.

3. As to future pregnancy: Elective section for this patient will prevent any danger during labor, and so labor is not discussed.

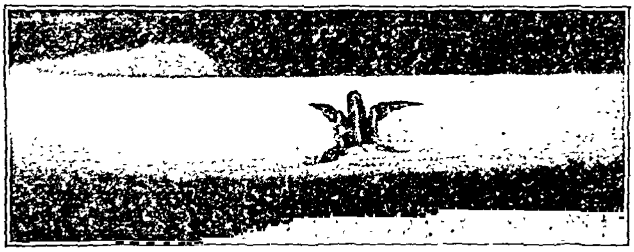
Lack of space prevents lengthy consideration of the prognosis during the prenatal period. This is summarized by the following, quoted from "Cesarean Scars," by Greenhill and Bloom (The Journal, Jan. 5, 1929, p. 21): "In the entire world literature . . . no uterus ruptured during pregnancy" (following low cervical cesarean section).

Harry S. Fist, M.D., Los Angeles.

POSSIBLE CAUSE OF EXPLOSIONS IN GAS ANESTHETIC DEVICES

To the Editor:—Recently a harmless explosion occurred here which well illustrates a possibility about which I have spoken before; namely, that flushing the anesthesia machine with oxygen rather than with nitrous oxide, before all the ethylene and ether have been removed, may lead to an explosion.

The anesthetist had been giving ethylene and oxygen. After the operation was finished, the machine was shoved into a corner. The anesthetist then emptied the bag by bringing pressure to bear on it with her hand, and then flushed the machine with oxygen. She tried to take the inhaler tubing from the machine, and there resulted a quick explosion. This occurred even though our anesthetists have been warned repeatedly against this particular procedure. The enclosed print shows the hole that was made in the breathing tube. In some way or other the ground wire had become disconnected from the machine, so that it was not attached at the time of the explosion. As has been said, no harm was done in this instance because the machine was far removed from the patient.



Hole made by explosion in breathing tube.

On a small scale this illustrates exactly the situation that is being met generally throughout the country when the gas machine is flushed with oxygen instead of with nitrous oxide.

John S. Lundy, M.D., Rochester, Minn.

"NUTRITION AND MILK PRODUCTION"

To the Editor.—I was much interested in the editorial in The Journal, June 4, on "Nutrition and Milk Production," and particularly the losses of calcium and phosphorus during the height of milk production.

In an extended study of this subject with cows it has been fairly well shown that the losses of calcium in the height of milk production is a process that cannot be stopped by high injections of vitamin D. It appears to be a normal physiologic process, no doubt induced purposely by an overactive parathyroid gland, which is known to influence the abstraction of calcium from the skeleton and for the purpose of maintaining the calcium levels of the blood normal during the unusual draft of calcium and phosphorus in mammary secretion.

When the parathyroid fails to function at the initiation of lactation, "milk fever" in cattle results. This can be corrected by the injection of parathyroid hormone. "Milk fever" in cattle is a low blood calcium followed by tetany.

Research Bulletin 112 of the University of Wisconsin College of Agriculture shows that in spite of the mineral losses from the skeleton at the height of lactation, as milk flow recedes with progressive lactation, storage of calcium and phosphorus becomes large. The skeleton is as well mineralized for the next lactation, provided there was a rest period between calves, as in the preceding lactation.

E. B. Hart, Madison, Wis.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

NAPHTHA POISONING

To the Editor:—A woman, aged 31, has been employed for fourteen months rolling rings on wet balloons as they return from the dipping room, where they are dipped in naphtha. The symptoms that she presents include dizziness, headache, nausea, tremors of the hands, pain and tingling of the hands and feet, general weakness, malaise, loss of appetite, spots before the eyes, nervousness, irritability, loss of weight, a general run down condition and weak pulse. Examination of the chest is negative for tuberculosis. The heart is slightly enlarged. The pulse is weak and thready. There is a slight anemia. The urine is normal. The blood pressure is 114 systolic and 70 diastolic. The diagnosis is naphtha poisoning. How would this affect the heart and the general condition of the patient? Please omit name. M.D., Ohio.

Answer.—The term "naphtha" is loosely applied to several forms of petroleum derivatives, ranging from the low flash gasoline or petroleum benzin through Stoddard's Solvent. From the point of view of toxicity, the chief differences center about vaporability. Whatever the type may be, the following answer is reasonably applicable.

The vapors of naphtha possess about one half to two thirds of the toxicity of benzene (benzol). The manifestations are much the same except with respect to blood changes; when they are due to naphtha, the blood elements are far less affected than when they are due to benzene. Concentrations of naphtha in excess of 0.45 per cent of the vapors may be expected to produce harm if the exposure period exceeds one or two hours. Concentrations of 2.5 per cent may kill in a few minutes. Mild, acute involvement is well known in industry as a "naphtha jag." All the signs and symptoms mentioned in the query may arise. In addition, in slightly severer form, a bronchitis or other evidence of inflammation of the respiratory tract may arise, including, in rare cases, pulmonary hemorrhage.

At necropsy of animals exposed to naphtha, the heart muscle has been found to be suffused with blood. Granular degeneration of the liver and nephritis has been established.

The chronic form of naphtha poisoning presents profound drowsiness or alternating drowsiness and insomnia, rarely sudden onset of unconsciousness, jaundice or bile in the urine, a mild degree of anemia and leukopenia, loss of weight, increased reflexes, sluggish pupils, and abnormalities of taste. On other occasions, chronic naphtha poisoning resembles multiple sclerosis associated with a hepatitis.

MANTOUX TEST

To the Editor:—Could you inform me as to the value of the Mantoux test? I should be glad if you would indicate by whom it was developed and when. Donald E. Miller, M.D., St. Peter, Minn.

Answer.—The intradermal tuberculin reaction, described independently by Mantoux (*Compt. rend. Acad. d. sc.* **147**:355, 1908) and Mendel (*Med. Klin.* **4**:402, 1908), has been regarded for years as the preferred method. It is more certain of producing a reaction than the simpler Pirquet test, and less objectionable than various other methods.

It affords one of the most certain methods of establishing the presence of a tuberculous infection. This cannot be done, however, without a consideration of age, dosage, condition, and size of a quiescent lesion.

The age of the individual is of importance because a positive reaction in children under 6 years of age usually means an active tuberculous infection. The infection may be chiefly in the lymph nodes, but there rarely has been time for any infection to become quiescent. In an older person a moderate reaction may be present when the tuberculous lesion may be entirely latent without possessing any clinical significance. If the reaction is violent, however (producing a reaction from 1.5 to 2 cm. in diameter), especially with a small dose of tuberculin, it is significant of active infection, even in an adult.

The quantitative aspect of tuberculin is also important. Some begin by using a dosage of 0.01 mg. and stepping up to 0.1 and finally to 1 mg. in 0.1 cc. of saline solution. Usually 0.1 mg. is the starting dose; certainly no more than this should be used in an unknown patient for fear of causing a destructive focal reaction. If this is negative, it is indicative of nothing more, at the most, than a quiescent tuberculosis in the great majority of patients. If 1 mg. is then given and found negative, the test is almost surely negative. In certain rare conditions, such as measles, severe diseases, or terminal or overwhelming tuberculosis, the patients may lose their reactability. In this event it is always well to repeat the test if possible for one or two monthly intervals.

Finally, it is not known with certainty what the least size of a quiescent or latent lesion is that will fail to cause sensitivity. It seems evident at times that there are many small lesions that may not produce a reaction with any size of dosage. Such conditions are, however, not many and are relatively unimportant.

ACNE

To the Editor:—I would appreciate your help in the following case: My daughter has what has been diagnosed by a competent dermatologist as acne, which is mostly on her chin. She is 19 years old and has a strictly negative history in every respect. These "pimples" pop out through the skin at irregular intervals, some of them getting to be half as big as a split pea. Some of them contain pus or a little "core." Sometimes the eruption is worse just preceding menstruation. The menses are regular and there is no cramping. There is a very small enlargement of the thyroid, but it is not toxic. She keeps herself scrupulously clean, and uses a bland soap and face cream. She has taken eight x-ray treatments; she took four, two weeks apart, rested a month and took four more treatments, two weeks apart. This improved the condition for a short time. She also used various sulphur lotions and ointments as prescribed by the dermatologist. She has taken some Finsen light treatments also, which I gave her myself. She eats little meat or carbohydrates. After one of these "pimples" leaves, it leaves a small scar which remains. I have given the patient cod liver oil, also. Please do not publish name or address.

M.D., Indiana.

Answer.—This is the usual history of the adolescent type of acne, which frequently disappears after marriage. The treatment has been along approved lines. Most dermatologists advise an initial course of roentgen therapy in one-fourth skin unit doses once weekly for from eight to twelve weeks. If the acne persists or recurs, roentgen treatment should not be persisted in, and mild ultraviolet treatments may be used as an adjunct. Proper internal treatment and a careful dietetic regimen will control many cases of acne.

In general, an excess of carbohydrates derived from sweets and starchy foods, fats and fried articles should be avoided. It is particularly important not to use iodized salt in cooking. Bromide and iodide tablets and tonics containing iodine may be harmful. An excess of milk is to be avoided. Among the articles prohibited or at least limited are candies, chocolate, ice cream sodas, sundaes, malted milk, rich pastry, mince pie, fresh bread, waffles, griddle cakes, maple syrup, fried sweet potatoes, spices, pork and beans, breakfast sausage, salted nuts, Camembert cheese, Welsh rarebit, and fried foods in general.

The diet should contain an abundance of fresh vegetables, fruits, cereals, plainly prepared meat or fish, and simple desserts. Regularity of meal times and proper chewing of food are essential.

In the care of the skin, massage, facial treatments, face creams and unnecessary manipulation of the lesions must be avoided. A mild superfatted soap should be used daily with warm water followed by cold. If the skin gets dry during a course of treatment, a cold cream may be used at night.

A small percentage of cases can be cured by home treatment with suitable internal and external remedies. Improvement is often slow and uncertain. Yeast has an undetermined usefulness. Mild laxatives should be taken if necessary. Vaccines and serums are occasionally beneficial. Specific instructions for internal medication should be followed.

The object of local treatment is to overcome the excessive oiliness of the skin by reducing the activity of the oil glands and to check the tendency to formation of blackheads and papules. Lotions and salves should be used only when prescribed. Comedones and pustules are best evacuated by the physician using sterile instruments. Modern radiation treatment with roentgen and ultraviolet rays will cure a large percentage of cases if carried out regularly and systematically once weekly for from eight to twelve weeks. Scarring and pitting are minimized by early treatment. Recurrences can be prevented by adhering to a correct diet and by attention to the hygiene and care of the skin.

PARTIAL PARALYSIS AND MUSCULAR ATROPHY AFTER LABOR AND SYMPHYSIOTOMY

To the Editor:—What could be the causes of partial paralysis of the hip and leg following symphysiotomy? A woman of 19 was subjected to this operation as the safest procedure to relieve her of an impacted brow presentation. The symphysis was sutured with heavy absorbable suture, the hips were swathed in adhesive plaster, and she was placed on a Bradford frame for about three weeks. There was paralysis of the bladder necessitating catheterization while she was in bed, but since delivery had been quite difficult this was not thought to be remarkable. At the end of five weeks she began to try to walk with care, and because she complained of right sacro-iliac pain she was fitted with a sacro-iliac belt. But in the following two months she had not improved in her ability to walk. The muscles of the right hip and buttock are painful and show decided atrophy. She drags the right foot in walking and cannot lift it from the bed. The right ankle is very weak and the right knee jerk is greatly exaggerated. The nerve supply of the muscles involved has its origin high above the field of operation. Yet Painter, reporting a somewhat similar case in the *Boston Medical and Surgical Journal*, June 22, 1916, says: "Convalescence was very slow and painful and she experienced great difficulty in walking. She was almost paralyzed in both legs." But how could the operation or the following sacro-iliac strain produce paralysis, especially with atrophy? Could the spinal anesthesia in this case have been a contributing factor? Could a mild diphtheria eight years ago, or an unrecognized poliomyelitis four years ago be possible causes? Would not the exaggerated knee jerk on the affected side indicate a lesion higher up even if there were no other signs or history of such lesion? Even more important, what should the treatment be? Would continued rest for a year be better than encouraged exercise?

Harold C. Miller, M.D., Eglon, W. Va.

Answer.—The paralysis and atrophy probably resulted from pressure on the lumbosacral trunk during delivery rather than being related to symphysiotomy. The sacro-iliac pain is likely due to neuritic symptoms but it is possible that the pain has resulted from sacro-iliac strain during the symphysiotomy. Spinal anesthesia has occasionally produced symptoms of transverse myelitis but is probably not a causative factor in this case. The history of diphtheria eight years previously is not responsible, nor could there have existed a poliomyelitis without producing more evident signs in the light of the present situation. An aggravated knee jerk naturally indicates an upper motor neuron disease, and if that is present in this patient one must naturally suspect a lesion situated in the cord rather than in the lumbosacral roots. In that event one would have to consider the possibility of a localized myelitis.

Rest, in order to avoid fatigue, is an important factor in the treatment, but massage, passive motion and even mild active motion will do more in hastening recovery than mere rest in bed. If a foot drop is present, the foot should be supported by a right angle foot brace to avoid overstretching of the extensor muscles.

TREATMENT OF VAGINITIS

To the Editor.—A girl, aged 5, has a gonorrheal vaginal discharge of one and one-half years' duration. Treatment included serums and irrigations of antiseptics. The discharge has subsided, though not completely. Recently I used Presojod; while beneficial, it has not effected a cure. Smears are positive. What further treatment would you advise? Please omit name and address.

M.D., Pennsylvania.

Answer.—The most important factor in the management of the case is to attempt to locate the source of the gonococci. Careful examination of the urethra, particularly of Skene's tubules, and a vaginoscopic examination by means of an illuminated vaginoscope or female urethroscope. If the infection originates in the cervix, topical applications may be made through the vaginoscope with mercurochrome-220 soluble or weak silver solutions. If Skene's glands are involved, irrigation with 5 per cent mercurochrome solution through a blunt pointed soft silver cannula should be carried out. Good results in these cases have been obtained when using daily instillations into the vagina of 1 per cent mercurochrome ointment (Stein, I. F.; Leventhal, M. L., and Sered, Harry: Cervicovaginitis, *Am. J. Dis. Child.* **37:**1203 [June] 1929). A cure usually is obtained in from ten to twelve weeks by this method if the technic is followed exactly.

IMMUNIZATION AGAINST DIPHTHERIA

To the Editor:—A child was exposed to a case of laryngeal diphtheria by hugging and kissing the child with the diphtheria. The exposed child is 3 years old. Would it be better in this massive exposure to give an immunizing dose of antitoxin or wait and give a large dose of antitoxin if the child developed diphtheria?

L. J. Rutledge, M.D., McComb, Miss.

Answer.—Formerly it was general practice to give an immunizing dose of antitoxin to persons who had been exposed to diphtheria with the idea that it was harmless. It is now known that even a small primary dose of serum may produce alarming and serious reactions. It may also render the individual sensitive to serum administered subsequently. With the multiplication of immunizing and therapeutic serums and their more general use, it has become apparent that hypersensitiveness to subsequent injections of serum should not be established when it can be avoided.

In the case described, it is not at all certain that the second child had received an infecting dose of diphtheria bacilli. The practice followed might well vary with circumstances. If the exposed child cannot be closely watched for the first signs of diphtheria, it would be wise to give an immunizing dose of antitoxin. If, however, the child can be intelligently watched and given a suitable dose of antitoxin at once should signs of diphtheria appear, there would be no disadvantage in waiting. In this way an annoying or serious serum reaction might be avoided, and sensitization to subsequent administration of serum obviated.

ICHTHYOSIS

To the Editor:—My son, who is now 17 years of age, has been afflicted with ichthyosis since 3 or 4 years of age. He is much worse during cold weather. During the summer his skin is soft and does not scale. Local remedies seem to do him no good He complains that baths make him worse. What would you recommend as the best treatment? Would the violet ray do him good? Please omit name.

M.D., Pennsylvania.

Answer.—The chief reason that ichthyosis improves in summer is probably that there is more perspiration then, keeping the skin soft. Measures to increase perspiration should therefore be of some help in the winter. Hot baths or sweat baths followed by a cold douche and a rub, and before the skin is quite dry the application of a bland oil or ointment, should be tried. Soap should be avoided as much as possible. Ultraviolet rays tend to dry the skin. A humid atmosphere within doors overcomes part of the drying effect of winter.

DIAGNOSIS AND TREATMENT OF DIARRHEA

To the Editor:—A man, about 55 years of age, who has never had any previous serious illness, stopped in Iowa to visit relatives, about a year ago, while driving home from Florida While there he had an attack of indigestion, and a physician advised him to use Lacto-Dextrin (Battle Creek). After a few days he developed a severe diarrhea, which he has been unable to control at any time since. This man is a druggist and has taken bismuth, kaolin and opiates without success. What treatment would you suggest? Please omit name and address.

M.D., North Dakota.

Answer.—This case demands a complete diagnostic appraisal, as the causes of diarrhea are varied and many. Before a plan of treatment can be outlined, an attempt at diagnosis must be made. In addition to the history and physical examination, the following studies should be carried out: microscopic, chemical and cultural studies of the stools; secretory function of the stomach, duodenum and pancreas; roentgenologic studies of the stomach, intestine and biliary system. One must make certain that parasitic infestation is not an etiologic factor. The treatment is dependent on the cause.

SPINAL ANESTHESIA IN LABOR

To the Editor:—Please give your opinion on the routine use of spinal anesthesia in normal confinement cases. One of the local physicians injects 100 mg. of procaine hydrochloride into the spinal canal to relieve the pain of the second stage of labor. Many of these cases require several injections of solution of pituitary and low forceps to complete delivery. I have never used this method but the patients say that they feel no pain after the spinal anesthetic is given, and some seem to prefer this method of delivery. Please comment on using spinal anesthesia as a routine in normal cases in the second stage of labor. Please omit name and city.

M.D., Colorado.

Answer.—Spinal anesthesia is becoming safer with the improvements in its technic, but it still has a considerable mortality unless carried out with the most punctilious attention to minute details. This is true of its use in surgery and gynecology but it is more than true in obstetrics. Kroenig of Freiburg, as long ago as 1913, warned that spinal anesthesia was particularly dangerous in pregnant women, and experience in this country, as well as abroad, has justified this prognosis.

At a recent informal discussion by six obstetricians of note, fifteen deaths during delivery, all following spinal anesthesia, were reported as occurring within a few months.

There are safer anesthetics to assuage the pains of the second stage of labor, and spinal anesthesia should not be used as a routine.

ERYSIPELAS

To the Editor:—For two successive years I have suffered from attacks of facial erysipelas. Is there any reliable method of immunization that could be used to prevent or make less likely a recurrence? Please omit name.

M.D., Ohio.

Answer.—Recurring attacks of erysipelas usually start from some focus of chronic infection. This should be sought and, if found, it should be appropriately treated. Immunization with comparatively large doses of a standardized erysipelas toxin has given good results in a small series of similar cases.

MYDRIATIC FOR OPHTHALMIC EXAMINATION

To the Editor:—What would you recommend as a safe and rapid mydriatic for ophthalmoscopic examination of the middle aged and elderly as part of a general medical examination? Would you instil physostigmine (eserine) solution afterward as a precautionary measure against glaucoma? Please omit name.

M.D., Pennsylvania.

Answer.—Probably the simplest rapid mydriatic for ophthalmoscopic examination to the middle aged and elderly is a 2 per cent eucatropine (euphthalmine) solution. It is well to repeat the primary instillation with another drop five minutes later and within fifteen to twenty minutes the pupils will be sufficiently dilated for examination. The subsequent use of a miotic (pilocarpine, not physostigmine) is always a safe measure.

RELATIVE POTENCY OF CODEINE PREPARATIONS

To the Editor:—Please advise me concerning the relative strength of codeine sulphate, codeine phosphate and codeine alkaloid, especially with reference to their use in cough mixtures. Please omit name.

M.D., New Jersey.

Answer.—One hundred grams of codeine phosphate is equivalent to 73 Gm. of codeine; and 100 Gm. of codeine sulphate is equivalent to 80 Gm. of codeine. This means that a dose of the same weight of codeine is about one fourth stronger than the same weight of codeine sulphate and one third stronger than the same weight of codeine phosphate.

TREATMENT OF SOFT CORNS

To the Editor:—In The Journal, April 16, page 1402, was a query regarding the treatment of a soft corn. Soft corns usually occur between the toes near the base, and they may be disabling. Paring and softening with salicylic acid sometimes are not favorable. Corns may be treated satisfactorily, however, surgically.

After injecting well with a local anesthetic under the corn, one can readily remove the corn with a sharp curet such as is used for bone. It may take considerable pressure. The curet should be run around the corn so as to lift it out in one piece. It is surprising how deep some corns are. After the cavity has been touched with an antiseptic solution and simple dressings have been applied, they will readily heal. The pain after removal is less than before. After this treatment, they may not recur. If they do, a curative operation should be done.

Every corn is due to bony pressure either under the corn itself or from an adjacent toe. Palpation will show where this pressure is. Soft corns are frequently due to an overgrowth similar to an exostosis on the side of the metatarsal head. For a permanent cure a small incision should be made so that this projecting bone is exposed and then it can be removed with Rongeur forceps. The corn may or may not be removed at the same time with the curet. Two or three sutures suffice to close the opening, and the corn will be permanently cured.

These operations are described at length in the *Journal of the Michigan State Medical Society* for July, 1930.

J. G. R. Manwaring, M.D., Flint, Mich.

PERSISTENT MASTURBATION

To the Editor:—In the case of persistent masturbation discussed in Queries and Minor Notes (The Journal, April 30) your correspondent is told: "For this type of patient, marriage may be advised as it relieves the tendency to masturbate and would remove temptation of outside coitus with all the serious related possibilities."

This advice raises an important question: Is it ever justifiable to advise marriage as a remedial agent for sexually disturbed men? It is a common practice to recommend marriage in such cases as this, but we must remember that two lives are involved, not only one. Some of the most tragic cases that have come under my observation have been those in which marriage was prescribed as a cure for sexual dysfunction in men.

With all due respect to the authority who proffered this advice, I believe it is *never* justifiable, either in morals or in law. In the case under discussion, this advice seems particularly open to question, to say the least, first, because the man is a persistent masturbator for the pleasure it gives him and he will probably always prefer this practice to normal coitus; secondly, because he is admittedly more or less impotent.

It is true that he has managed to consummate the sexual act twice in the past six years—hardly enough of an achievement on which to base an estimate of his capacity for normal marriage. If he were not definitely impotent (psychically as well as physically), he would have seized on those two high spots in his sexual life and used them as a stimulus for the further substitution of normal coitus for masturbation. But no, he continued his masturbation, which clearly indicates either that he preferred that practice or that he could not accomplish the other.

In any event, with such definite sexual deficiencies, it is debatable whether marriage can be of any help to him, even though one felt disposed to allow a woman to become the innocent victim of the experiment in the fleeting hope that her physical propinquity might possibly stimulate into activity his latent normal sex powers, if there are any.

There is another thing to be said about this case. It is evident that this man is suffering from chronic seminal vesiculitis. I have seen not a few such cases either greatly improved or altogether cured through Belfield's vasotomy. This should be recommended, in addition to the other treatment, which seems to have helped him somewhat. When the man has been cured of his preference for masturbation and his normal potency has been established beyond question, it will then be in order to consider the advisability of marriage—but not till then.

A. L. WOLBARST, M.D., New York.

New York February Report

Mr. Herbert J. Hamilton, chief, Professional Examinations Bureau, reports the written examination held in Albany, Buffalo, New York and Syracuse, Feb. 1-4, 1932. The examination covered 9 subjects and included 10 questions. An average of 75 per cent was required to pass. One hundred and seventy-three candidates were examined, 119 of whom passed and 54 failed. Eighty candidates were licensed by endorsement from Jan. 1 to May 1, 1932. The following colleges were represented:

Medical Economics

AN EXPERIMENT IN COLLECTIVE MEDICAL SERVICE

Results of the First Year of Operation of the Bassett Hospital Annual Payment Plan

G. M. MACKENZIE, M.D.; MARJORIE F. MURRAY, M.D., AND MONROE A. MC IVER, M.D.
COOPERSTOWN, N. Y.

Many traditions apparently firmly rooted in our prewar social organization have been critically scrutinized, attacked, modified or abandoned during the last fifteen years. That the established relationship of the medical profession to the public is one of the institutions that are being subjected to reexamination and criticism is quite clear. The large number of contributions to various phases of this subject in both lay and medical periodicals indicates a widespread and increasing interest in the economic and social implications of medical practice.

Aware of this situation and stimulated by the frequent observation locally of families in the lower economic groups faced with embarrassing indebtedness because of the unavoidably high cost of essential diagnostic and therapeutic procedures, the Mary Imogene Bassett Hospital, at Cooperstown, N. Y., started on Jan. 1, 1931, a small experiment involving the principle of voluntary sickness insurance. In common with the numerous compulsory and voluntary sickness insurance schemes that have been in operation in Europe for many years, the basic idea was to distribute the cost of sickness evenly throughout a group, the individual members of which would require, during the term of insurance, varying amounts of medical attention. In contrast with nearly all the sickness insurance schemes that have been tried, the organization and operation of the Bassett Hospital Annual Payment Plan has been under the direction of a group of physicians. The element of outside official domination by state, municipality or insurance company has been completely absent in this scheme. It is entirely a physicians' undertaking.

THE MILIEU, PROFESSIONAL PERSONNEL AND MEDICAL FACILITIES

Cooperstown is a rural community in Otsego County, N. Y., with a population of 2,909; within a radius of 5 miles there are approximately 2,000 more inhabitants. This group of 5,000 people is composed of farmers, shopkeepers, clerks, skilled mechanics, unskilled laborers, employees of various types, and a few professional men and women. A very small percentage of the population is foreign born. During the summer there is an influx of perhaps 400 to 600 summer residents. The poor people of urban communities with access to low cost dispensaries and wards in city hospitals have far greater opportunities for medical and surgical care at minimal or no expense than the poor of such a rural district as Otsego County. The disadvantage in which individuals in the dispensary and ward-patient groups are placed in rural communities, as compared with a similar economic group in metropolitan areas, was one of the considerations which led to this experiment with the Annual Payment Plan.

The Mary Imogene Bassett Hospital consists of a group of four stone buildings with beds for eighty patients. It is equipped to do nearly all the modern diagnostic and therapeutic procedures, including electrocardiography, basal metabolic rate determination, x-ray diagnosis and therapy, radium treatment and physical therapy, and has laboratories for bacteriology, serology, pathology and biologic chemistry. The staff consists of nine physicians and surgeons, all of whom are on a salary basis, and all have their offices in the hospital. Fees for professional services, either in the hospital or at the patient's home, are collected by the hospital. Three interns, thirty graduate nurses and six laboratory assistants complete the professional personnel. It is a non-profit-making institution, enabled to operate with a deficit because of the generous philanthropy of a resident of Cooperstown. Two physicians not on the hospital staff have their offices in Cooperstown and carry on practices in the village and vicinity. One of these physicians, previously on the hospital staff, resigned his position at the hospital and opened an office for independent practice after the Annual Payment Plan had started. Thus, 90 per cent of the physicians of Cooperstown were on the hospital staff in January, 1931. The work involved in the operation of the Annual Payment Plan constitutes only a small fraction of the medical and surgical activities of the hospital.

PROVISIONS OF THE ANNUAL PAYMENT PLAN

The charges for membership are $25 a year for an individual, and $100 for an entire family of any size. Membership dues may be paid in monthly instalments. In return for this the hospital, through its staff, undertakes, in addition to an annual physical examination, to take care of the members of the Annual Payment Plan in case of any illness, either medical or surgical, without additional charge. The service includes physician's attendance, surgical operations, x-rays, laboratory examinations, ambulance service and medicines, except those administered over long periods of time, such as insulin, arsphenamine and liver extract. In case of admission to the hospital, ward service is provided; if a member of the Annual Payment Plan on admission to the hospital desires a private room, he is allowed a credit of $4 a day; with this deduction the charges for private room service, operations, laboratory examinations and professional fees are computed as for nonmembers. A prolonged illness involves no additional expense for the member up to the date of expiration of his membership. So far as practicable, and in conformity with the departmental organization of the hospital, a member of the Annual Payment Plan may select from the hospital staff the physician whom he prefers. The hospital, through its professional staff, reserves the privilege of deciding whether an illness is to be treated at the patient's home, in the outpatient offices of the hospital, or in a ward of the hospital. Obstetric cases are not included in the Annual Payment Plan service.

COMPOSITION OF THE MEMBERSHIP

In January, 1931, 182 applicants had been accepted for membership. In order to keep the number of members as nearly constant as possible throughout the year, no applicants were accepted after January. Of the 182 accepted applicants, 8 failed to make any payments and were therefore dropped after the first month. During the year 13 members, for various reasons, financial and other, failed to keep up their payments. There were thus 174 members who started and 161 members who continued through a full year. As it was desired not to make the standards of health required for admission too high, a number of applicants with known pathologic conditions were accepted. These were as follows: 16 individuals with hypertension, 3 with marked obesity, and 1 each with tuberculosis of the cervical lymph nodes, hypothyroidism, colloid goiter, secondary anemia, peripheral neuritis, chronic nasopharyngitis, fibromyoma of the uterus, diabetes, postencephalitic syndrome, chronic prostatitis, and rheumatic heart disease. Ten persons with pathologic conditions were accepted with the understanding that medical care for these conditions would not be included in the services under the Annual Payment Plan, but that

---

While this report is submitted by three members of the staff of the Mary Imogene Bassett Hospital, the entire staff participated in planning and carrying on the Annual Payment Plan. Miss K. M. Danner, superintendent of the hospital, and Miss Florence Saenger, secretary of the Annual Payment Plan, rendered invaluable service in the administrative work.

everything else would be treated without any charge in addition to the membership fee; this group includes one case each of chronic eczema, hernia, varicose veins, acne vulgaris, chronic arthritis, and deviated nasal septum, and four children needing tonsillectomies.

With regard to economic status, the group was not homogeneous. A large percentage of the members were wage earners with small incomes, school teachers, and elderly people living on small savings; the undertaking was planned primarily for this group of people; a small percentage of the members would be classed as economically in the middle class. Included in the membership there were thirty-eight persons whose memberships were paid for in full and twenty-five persons whose memberships were paid for in part, by employers or by philanthropic citizens. Among these members whose dues were paid by others there were a number of persons who, in case of illness, would have been cared for by the staff of the hospital but who would have been able to pay little or nothing. Lack of information on their financial resources makes it impossible to give exact figures for this group which would have been partially or wholly dependent on charity, but presumably from fifteen to twenty of these members would have been, in case of illness, to some extent dependent on charity.

TABLE 1.—*Membership and Cost of Service by Age Groups*

1 Age Groups in Years	2 Number of Members	3 Percentage Composition of Membership	4 Percentage Composition of Whole Population (U. S. Census 1930) Cooperstown Village	5 Otsego County	6 Cost of Service	7 Percentage Cost of Service	8 Number of Members Not Using Service	9 Number of Members Exceeding $25 Service
1- 4	9	5.2	5.6	7.3	$ 234.50	5.8	2	4
5-14	32	18.3	13.0	16.7	1,055.25	26.2	11	11
15-24	27	15.5	17.9	14.6	391.10	9.7	9	5

Totals	174				$4,037.35		53* (30.6%)	39 (22.4%)

* Nine of these members did not complete payments.

The distribution of the membership by age groups is shown in columns 2 and 3 of table 1. For comparison, the percentage composition of the population of Cooperstown and Otsego County in the different age groups is shown in columns 4 and 5. These figures are taken from the U. S. census of 1930. It will be seen that the membership was overweighted in the 5-14 and 35-44 age groups, and underweighted in the 25-34 and the over-65 age groups. In the other age groups the percentage figures for the membership were close to those of the whole population of the community.

The community received information of the plan first by the personal contacts of members of the hospital staff; then at meetings of the Rotary and Exchange clubs short addresses outlining the provisions of the Annual Payment Plan were made by members of the staff. The local papers reported the substance of the addresses and soon the facts were spread about the community. A representative of the hospital called on people said to be interested and offered to give any additional information desired. This representative was careful to state that the hospital did not wish to take as members those who were regular patients of physicians not on the hospital staff, and studiously avoided anything which might be called salesmanship. Following the publication of the news story in the local papers, newspapers throughout the United States received the story from the Associated Press and many of them printed brief accounts of the Annual Payment Plan. A leaflet stating the provisions of the plan was printed and sent to those whose names had been suggested as people who wished detailed information.

AMOUNT AND COST OF SERVICES RENDERED TO MEMBERS OF THE ANNUAL PAYMENT PLAN

In computing the value of services rendered to members of the Annual Payment Plan, the rates prevailing in the community for house and office calls were used. No schedule of fees has been adopted by the county medical society, but the prevailing charges may be stated to be approximately as follows: house and office calls, from $2 up; night calls, $1 additional; out-of-town calls, 50 cents a mile additional. The ward rate of the hospital is $4 a day, with an extra charge only for surgical operations. Fifty-three members (30.6 per cent) had no medical or surgical service during the year. The distribution by age groups of these nonusers is shown in column 8 of table 1. But in this group there were nine persons who dropped out during the year, leaving forty-four (27.3 per cent) members who completed the year without any medical attention. There were thirty-nine members who received medical attention for which they would have been charged more than $25 if they had not been members. The distribution of these members by ages is shown in column 9 of table 1. In columns 6 and 7 of table 1, figures are given by age groups for the cost of services rendered and the percentage for each age group of the total cost of services rendered. These figures show that the 5-14 group was the most costly one to carry. It constituted 18.3 per cent of the membership, and the services rendered to it amounted to 26.2 per cent of the total. The 35-44 group, on the other hand, constituted 23 per cent of the membership and received only 14.8 per cent of the medical services rendered.

During the year the members made 560 calls at the doctors' offices in the hospital, and there were 115 visits by doctors at the patients' homes. There were 381 patient-days for those admitted to the hospital. The computation of the cost of the outpatient work and medical service rendered to inpatients is shown in table 2.

Thus, the total amount that would have been charged for the professional services rendered if the patients had not been members of the Annual Payment Plan would have been $4,037.35. To this should be added, in order to determine the total cost of operating the undertaking, $310 for postage, stationery and secretarial service, and $305 for the admission examinations. Since many of the applicants had recently been patients of members of the hospital staff, the amount of work involved and therefore the amount chargeable against the operating expense of the Annual Payment Plan was less than it would have been if all the applicants had required complete examinations. A proportion of the administrative expense—impossible to calculate accurately—is a nonrecurring expense, occurring only during the first year of operation. The total cost of professional services of all kinds and administrative work, therefore, came to $4,652.35. Against this the total receipts were $3,856.50, which sum was added to the general hospital fund.

TABLE 2.—*Cost of Service Rendered*

Outpatient Service:		
Professional fees	$1,610.00	
Pharmacy	42.40	
Laboratory	145.00	
Diathermy, massage, etc	80.95	
X-rays	177.00	
Radium treatment	40.00	
		$2,095.35
Inpatient Hospital Service:		
Professional fees	$ 714.00	
Room and board (including laboratory, x-ray and pharmacy charges)	1,143.00	
Operating room	85.00	
		1,942.00
		$4,037.35

In computing the cost of operating the Annual Payment Plan, no allowance has been made for bills that would not have been paid. It has been figured as though collections would have been 100 per cent of bills rendered. As the hospital has never for a year averaged more than 75 per cent collections, a deduction of 25 per cent should be made from the figure representing the cost of professional services rendered to members. This deduction amounts to $1,009.34. Among the members there were a number of nearly destitute persons and families whose memberships were paid for by others. In case of illness, some of these poor people would have been ineligible for county aid and would have been cared for by the hospital without any charge. Without making any allowance in comparing the two sides of the ledger for this indeterminate factor, the financial aspect of the experiment may be summarized as in table 3.

TABLE 3.—*Financial Aspect of Annual Payment Plan*

Total receipts from membership dues			$3,856.50
Service rendered	$4,037.35		
Less 25%, bills uncollectable	1,009.34		
		$3,028.01	
Administrative expense		615.00	
			3,643.01

THE DOCTOR-PATIENT RELATIONSHIP; ATTITUDE OF MEMBERS

An argument that has been advanced against the organization of medical practice along the lines of this experiment is that patients will make unreasonable demands on the physician if no extra expense is involved. It has been said that the doctor would be summoned at night or at other inconvenient hours when the patient could easily come to the office during office hours, and that patients would demand admission to the hospital when admission was unnecessary. The experience of one year with this particular group of individuals on an annual payment basis has falsified these predictions. In no instance has the patient made unreasonable demands or attempted to "get his money's worth" when no medical attention was necessary. The physicians on the hospital staff are unanimously of the opinion that there has been excellent cooperation on the part of all the members. Possibly, because it involved no additional expense for the patients, the doctors made a few more visits than they would have made for the same illnesses of nonmembers. That the members feel satisfied with the relationship is shown by the response to a questionnaire that was sent to all the members after the scheme had been in operation ten months. Not only was there no expression of dissatisfaction among the 162 replies received, but nearly all the members wrote that they considered it highly satisfactory. One hundred and thirty-eight reported a desire to renew their memberships; of those who did not wish to continue their memberships, seven had moved away from Cooperstown, eight were undecided because of finances, four preferred commercial sickness insurance—these were all part-time residents of Cooperstown—and one family of five preferred to be cared for by a physician not on the hospital staff.

CONCLUSIONS

It is not our purpose in this paper to argue for or against the organization of medical practice on an annual payment basis. We are fully aware of the multiplicity of factors—psychologic, economic, social, personal—involved in the relationships of the medical profession to the public. We have merely recorded certain facts which have come out of the first year of operation of a small undertaking in collective medical service carried on in a rural community in New York State. They apply only to a particular group of individuals and a particular group of doctors, working under a particular set of conditions which are far from typical.

Book Notices

The Technique of the Non-Padded Plaster Cast. By Fritz Schnek, M.D., First Assistant at the Accident Insurance Hospital in Vienna. With a preface by Lorenz Böhler, M.D., Director of the Accident Insurance Hospital in Vienna. Authorized English translation by Douglas D. Toffelmier, M.D. Cloth. Price, $5. Pp. 139, with 169 illustrations. Vienna: Wilhelm Maudrich, 1932.

For many years the author of this book has been first assistant to Prof. Lorenz Böhler, who popularized the method of treating fractures by reduction under local anesthesia and the immediate application of a nonpadded cast. In the preface, Böhler emphasizes the fact that the treatment of any fracture has two constant requirements; namely, good reduction and uninterrupted fixation until bony union takes place. He explains that many of the poor results that have occurred in the treatment of fractures were due to the fact that casts were applied on limbs with poorly reduced fractures and that faulty technic in the application permitted the fragments to slip, resulting in serious deformities. Schnek considers plaster of paris the best and least expensive material for splinting fractures because of ease of application and stability. The translator worked with the author for two years at the hospital and was therefore able to observe and learn the technic, a description of which he was called on to translate. This is an unusual situation, because most translators perform this work mechanically.

All fractures should be subjected to the roentgen ray immediately after reduction. The strength of the rays should be increased about 10 per cent and the exposure 50 per cent longer than usual when they must penetrate a cast. The nonpadded cast allows for a more even shadow of the bones and soft structures than does the padded cast. Schnek uses a thermophore or a hot-air box on the drying cast. While a cast is hardening it is often allowed to rest on a hard substance, such as the operating table or a chair, thereby causing an indentation which may be harmful.

One of the criticisms of the nonpadded cast concerns the patient's hair. The hair caught in the plaster dies in about three weeks and pulls out of the skin easily. The skin, instead of being bald when the cast is removed, is covered by a new growth of fine, downy hair, which is not adherent to the cast. It is easier to remove a nonpadded cast than one of the padded variety and it is not necessary to wet the cast with water or vinegar. If a cast is causing pressure, removal of all constrictions should restore normal circulation in about ten minutes.

The term "window edema" is used for the condition of swelling that develops through the window trimmed out of a cast. The edema is caused by internal edema of the soft parts pushing the muscles and skin out through the window, where the external pressure has been removed, causing a local edema of the skin. Enlarging the window will not remedy this condition; one must restore the external pressures.

In using plaster cast treatment, the physician is obligated to care for the patient from the time of its application until the time of its removal. All correction of position should be accomplished before the plaster has hardened, to prevent wrinkles on the inside of the cast. This is illustrated clearly by line drawings.

The author defines the duties that plaster casts are called on to perform; viz., general fixation of a portion of the body, maintenance of a definite position of certain parts of a limb, elimination of undesirable muscle movements and stresses, protection of the soft parts involved, aid in the final fixation of the part, and immobilization of infected or clean wounds. He emphasizes the importance of immobilizing the joints above and below an infected region. He quotes Böhler's first law of functional treatment as follows: "Continuous, never interrupted immobilization of all fractured or infected parts, including those adjacent to those joints capable of much movement, is necessary to avoid pain." The two facts that apparently make the padding of a cast necessary are (1) pressure disturbances of the skin and (2) circulatory disturbances. The most striking point in favor of the nonpadded cast is its ability to maintain the fragments in position and allow an early discharge of the patient.

Schnek describes the preparation of a plaster bandage. He uses the plaster splint, reinforcement or "reverse" as the basis of most casts because it can be molded easily to the contour of the part and because it adds greatly to the strength of the cast. The skin is not oiled or shaven. He warns against the danger of circulatory disturbances produced by plaster of paris. The surgeon is responsible for the patient from the time he applies the cast until he removes it. He cautions interns and nurses to be on guard continually for various signs and symptoms of trouble, such as change in color, swelling mobility, sensation and pain. In doubtful cases, the cast should be split or removed immediately. Regardless of the skill and training of the surgeon and assistant, the fresh fracture cases should be seen twice daily. The night nurse should be especially instructed and warned of the danger of negligence. The physician is responsible in court for all surgical accidents.

The dorsum of the toes must remain uncovered to allow their free movement and so that they can be readily observed for circulatory disturbances. A perfectly fitted cast never causes discomfort or pain; hence all complaints should be investigated immediately, windows cut, and pressure restored.

The knee joints should always be fixed in extension, because it is only in this position that the quadriceps muscle can be active and not undergo atrophy.

Schnek advises against the mistake of immobilizing fractures in an overcorrected position. He describes the method of wedging casts to correct the angulation of fragments. Making a walking cast too short is one of the most frequent errors made. It is wiser for the operator himself to hold the leg and allow the assistant to apply the cast. Extension or traction must be maintained until the cast has set. He emphasizes, in hand casts, the importance of free extension and abduction of the thumb and allowing complete flexion of the metacarpophalangeal joint of the little finger. The proximal finger joint should never be held in overextension.

Schnek omits a description of a cast to immobilize the shoulder girdle or shoulder joint because such a cast is of little or no value. He advises an airplane splint either factory made or constructed of Cramer wire by the operator.

Volkmann's ischemic paralysis, he explains, is produced as follows: The arm is markedly shortened and the proximal fragment of the humerus is dislocated anteriorly. The lower jagged edge of the proximal fragment compresses the brachial artery and vein against either of the distal fragments of the forearm bones. At times, the vessels may even be severed by the edge of the humerus. If reduction is attempted by acute flexion at the elbow without longitudinal traction, blood vessels and nerves will be compressed, and ischemia or even gangrene may result even though no cast is applied. If the reduction is accomplished with longitudinal traction on the humerus with the elbow held at a right angle, the vessels will be relieved of compression and normal circulation will be quickly reestablished. A cast applied at this time affords danger other than that attending the treatment of any fracture. The fingers must be watched for cyanosis and secondary swelling of the forearm, and the cast must be split as usual to control it. Volkmann's ischemic palsy, he says, never follows any but a supracondylar fracture and is rarely found following other elbow injuries. In the treatment of flatfoot, in which there is a supination contraction of the forefoot, the forefoot must be pronated in relation to the heel; at the same time it must be slightly adducted.

The exposition is clear and concise. There is much repetition, but it is desirable. In the preface by the translator and the foreword by the author, there are several points of information. The illustrations are mostly reproductions of photographs and diagrams of plaster casts and plaster technic. The author illustrates proper and improper methods. There are many errors in translation, but one overlooks these because the book was written in German and translated and edited in Austria. Regardless of whether the surgeon uses the nonpadded plaster cast or not, the book contains so much good information that it is well worth reading. It should be of value to every general, industrial and orthopedic surgeon and to the nurses and interns connected with hospitals where plaster of paris is used.

What the Public Should Know About Childbirth. By Walker Bourne Gossett, M.D. Cloth. Price, $2. Pp. 290. Minneapolis: Midwest Company, 1931.

This book is introduced with the statement: "This book . . . is a direct result of a paper sometime read by the author . . . on "Problems Pertaining to Obstetrical Practise in Catholic Hospitals." The author has incorporated in the book a chapter on this subject, perhaps the original article itself. Most of the book consists of rather long excerpts from articles written by the leading and lesser obstetric teachers in the country, but there are also citations from Arthur Brisbane and the Chicago *Tribune*. Chapter IX is a complete reprint of an article devoted to frontier nursing. There are two reasons why the book may lead to harm. The outside cover and almost all of the first sixty-three pages repeat the gross falsehood that "the United States is behind at least twenty other countries in its efficiency in the prevention of maternity deaths." That obstetrics in this country can and should be vastly improved is accepted by all, and this statement should be emphasized at every opportunity; but that our maternal death rate is so much higher than it is in countries whose vital statistics are either inaccurate or incomplete is absolutely not true. The author would do well to read Haven Emerson's article entitled "Factors Leading to Misinterpretation of Maternal Mortality Rates" in the April issue of the *American Journal of Obstetrics and Gynecology*.

The second source of harm is the author's insistence that obstetrics should be divorced from gynecology and that cesarean sections should not be performed by obstetricians but by general surgeons. In support of his argument he quotes the following statement from the late Dr. Williams: "One of my former assistants . . . informed me that last year in one of the hospitals in Houston, Texas, 102 cesarean sections were performed. Fifty-two were done by various members of the staff with 18 deaths as compared with 50 performed by himself and his partner with a single death, a mortality of 35 and 2 per cent, respectively." What Gossett does not mention, however, is that the 35 per cent mortality occurred in the hands of recognized surgeons and physicians, whereas the low death rate occurred in the practice of those who specialized in obstetrics. Is any further argument necessary? Gossett also makes the statement that "an obstetrician in his own private practice does not see enough cases that will demand a cesarean section." This surely is a strange sentence when one recalls the large series of cesarean sections reported by Williams, De Lee, Greenhill, Phaneuf and others. It is true that the private practice of these individuals was greatly supplemented by their ward services; but such experience is necessary for all authorities in all branches of medicine.

The material in this book could easily have been condensed into one-fourth the number of pages or less. Parts of the book were more properly written for physicians than for laymen, as for example the chapter on Catholic hospitals. The author misinforms his public when he states that "the sex of the child is already determined in the ova (eggs) in the ovaries of the girl, even before puberty. . . . It is a matter of Providence whether a male or a female ovum (egg) is the one fertilized by the male element." The accepted belief today is that, in human beings, ova are of one kind, whereas the spermatoza determine whether a child is to be a male or a female. When a spermatozoid with twenty-four chromosomes fertilizes an ovum, the child will be a female; whereas when a spermatozoid with twenty-three chromosomes fertilizes an ovum, a male will result.

Urine Analysis. By Byomkes Das Gupta, Bengal Medical Service. Cloth. Price, Rs. 3; 5/-. Pp. 141, with illustrations. London and Calcutta: Butterworth & Company, Ltd., 1932.

The author has been a teacher of medical students. This little volume represents the notes which he has given in lectures and demonstrations to the students on the subject of urine analysis. It was prepared in book form at the request of former students, who desired to have these notes in a handy form to use in practice. The chapters are on physical examination, chemical examination, microscopic examination and special examination. The last chapter, which is brief, takes up four special urine tests. There is an appendix in which the formulas are given for the various reagents used in urine analysis.

A Comparative Study of a Nursery-School Versus a Non-Nursery-School Group. By Ethel Kawin and Carolyn Hoefer. Assisted by Edna Mohr, Maria G. Linder and Marian W. Taylor. Based upon studies made by the Elizabeth McCormick Memorial Fund and the Institute for Juvenile Research assisted by the Behavior Research Fund. Paper. Price, 75 cents. Pp. 52. Chicago: University of Chicago Press, 1931.

The object of this study was to determine whether or not there are measurable differences in growth and development between children 2 and 3 years of age attending nursery schools and children of the same age who do not attend such schools. Psychologic tests, medical examinations and home observations of the children were carried out, while a social history, including a record of environmental factors regarding the home and family life, were obtained. As a result of this study it was found that, so far as physical growth was concerned, the two groups were about equal. Nor was there any marked difference between the nursery school group and the other children in mental growth. However, the nursery school children seemed to show improvement through the elimination of undesirable habits and the acquiring of more good habits. This study is too limited to allow definite conclusions to be drawn as to the results of nursery school training. The workers point out that it is merely a preliminary report to be used in formulating a larger research project.

Électrocardiographie clinique. Par Pierre-Noël Deschamps, médecin-assistant du service de cardiologie à l'Hôpital Lariboisière. Préface du Professeur A. Clerc. Paper. Price, 30 francs. Pp. 192, with 75 illustrations. Paris: Masson & Cie, 1932.

The author is an assistant to Professor Clerc, a recognized authority on electrocardiography in France. The work is a detailed presentation of clinical electrocardiography, tersely written and logically arranged. The experimental basis of the subject is discussed. There is a correlation of electrocardiographic observations with the symptomatology and basic pathology of the various conditions in which graphic methods are of importance in diagnosis, prognosis or treatment. Chapters discussing the value of electrocardiography in prognosis and in the management of acute infections, including acute rheumatic fever, diphtheria and scarlet fever, add materially to the value of the work. The book is well illustrated, most of the illustrations having been taken from more exhaustive publications by Professor Clerc. A carefully selected bibliography is attached, which includes the more important contributions on the subject and gives full recognition to American workers in this field of research. Whereas authorities may find certain statements at variance with their opinions, the clinician who reads French will find here a wealth of dependable information on clinical electrocardiography, which is unusually well presented. The work is a valuable handbook on the subject.

Biochemistry in Internal Medicine. By Max Trumper, Ph.D., Clinical Chemist and Toxicologist, and Abraham Cantarow, M.D., Instructor in Medicine, Jefferson Medical College. With a foreword by Elmer H. Funk, M.D., Sutherland M. Prevost Professor of Therapeutics at Jefferson Medical College. Cloth. Price, $5.50. Pp. 454, with 11 illustrations. Philadelphia & London: W. B. Saunders Company, 1932.

Modern medicine is so complex that the student can digest and use only a fraction of the subjects in the curriculum. Should he possess the ability to retain much of what is taught, it is highly improbable that he would possess also other qualifications that go to make the successful practitioner. For the sane and successful practitioner, dependence must be placed on the average student. Sane and practical training, therefore, should be available for his development. This can be accomplished only by avoiding unnecessary details and emphasizing fundamental principles. With a clear realization of these conditions in mind, the authors have endeavored to bridge the gap between the laboratory and the clinic, and to emphasize the important fundamentals of biologic chemistry as they apply to the practice of medicine. In doing this they have made an excellent selection of subjects and have presented it accurately and clearly. They discuss those parts of biochemistry of value in diagnosis and explain the basis for the tests used. The main subjects discussed are carbohydrate metabolism, with especial emphasis on diabetes; protein metabolism, with emphasis on its significance in nephritis, eclampsia and gout; cholesterol metabolism; chloride, calcium and phosphate metabolism; acid-base balance; basal metabolism; renal and liver functional tests; gastric function and tests; pancreatic function; cerebrospinal fluid and miscellaneous urinary observations. All subjects are treated adequately and clearly, and the meaning of each test is explained so lucidly that the reader may easily obtain an understanding of the chemical changes responsible for the symptoms. The great service of biochemistry to internal medicine is so well presented that it does credit to both these subjects.

Anatomie élémentaire des centres nerveux et du sympathique chez l'homme: Vie de relation et vie végétative. Par P. Gilis, professeur d'anatomie à la Faculté de médecine de Montpellier. Second edition revised by J. Euzière, professeur de clinique des maladies mentales et nerveuses à la Faculté de médecine de Montpellier. Paper. Price, 24 francs. Pp. 234, with 37 illustrations. Paris: Masson & Cie, 1932.

This is a small compendium of elementary facts concerning the central nervous system and the sympathetic system. It cannot be used for either a text or a reference book but might serve the purposes of a student who wishes a bird's eye view of neuro-anatomy.

The Principles of Physical Education. By Jesse Feiring Williams, A.B., M.D., Professor of Physical Education, Teachers College, Columbia University. Second edition. Cloth. Price, $3. Pp. 468, with illustrations. Philadelphia and London: W. B. Saunders Company, 1932.

The second edition of this work has brought it down to date as to facts, tests and figures, but it remains essentially the same as the former edition, a logical, intelligent presentation of the development of a physical education program, the reasons for it, the nature of it, its proper objectives, and its place in the general educational plan. Some would feel that Dr. Williams, in his eagerness to emphasize the value of large muscle activities in education, needlessly minimizes the health values of these activities. No one will feel that he lacks background in the understanding of general educational problems and philosophy of life, or specific knowledge of the history and present status of physical education and its procedures. The book is valuable not only for students and teachers of physical education but also for general educators and school administrators, who should be intelligent about the integration of all organized educational efforts.

Über die neuere Entwicklung der chirurgischen Behandlung der Lungentuberkulose. Von Professor Dr. R. Nissen. Mit einem Geleitwort von F. Sauerbruch. Paper. Price, 6 marks. Pp. 16, with 85 illustrations. Berlin: Urban & Schwarzenberg, 1932.

This monograph from Sauerbruch's clinic deals with the latest developments in the surgical treatment of pulmonary tuberculosis. The indications for and limitations of intrapleural pneumolysis, partial thoracoplasty, and especially plombage, are discussed in relation to partial pneumothorax collapse, to paralysis of the diaphragm by phrenic neurectomy, and to the posterior and combined posterior and anterolateral extrapleural thoracoplasty. Extrapleural pneumothorax following pneumolysis is discussed and the treatment of secondarily infected tuberculous empyema briefly outlined. A test of cardiac function by having the patient breathe air under positive and under negative tension is referred to; mediastinal flutter and wound infection are briefly discussed as the most serious postoperative complications. A short table on end-results is included. The author states that improved technic and clearer cut indications will extend the usefulness of all accepted methods and will prevent failures that result from their improper or incomplete application. The monograph is recommended to all interested in the treatment of pulmonary tuberculosis.

An Elementary Manual of Physiology for Colleges, Schools of Nursing, of Physical Education and of the Practical Arts. By Russell Burton-Opitz, S.M., M.D., Ph.D., Attending Cardiologist, Lenox Hill Hospital, New York. Fourth edition. Cloth. Price, $2.50. Pp. 419, with 147 illustrations. Philadelphia and London: W. B. Saunders Company, 1932.

The publisher advertises that in this edition the author "brought his text immediately up to date, adding much new material." A perusal of the volume revealed that, in addition to two minor changes elsewhere, only one chapter had been revised—the one dealing with the internal secretions. But even this chapter has scarcely been brought up to date, as shown by the retention of the statement that the chief function of the suprarenal glands is to produce epinephrine. The good features of the book have been retained, as there are practically no differences between the successive editions.

Medicolegal

Implied Consent to Examination and Treatment

(Baxter v. Snow (Utah), 2 P. (2d) 257)

Baxter discovered that he did not hear well through his left ear. He was treated by the defendant, an otologist. Subsequently he attributed deafness in that ear to the treatment administered and sued for damages for alleged malpractice. He alleged that he went to the defendant to have wax removed from his ear and instructed the physician to remove the wax and to do nothing more. The physician, however, not only removed some wax, but, finding the drum diseased, he cleansed the ear and inserted a cotton pledget dipped in ichthyol. Baxter alleged that in the course of this treatment a eustachian catheter was passed and that after the catheter was removed he complained to the physician that he, the physician, had made him deaf. He continued under treatment, however, for some time thereafter. The physician testified that during Baxter's first visit he did not use a catheter. The jury rendered a verdict in favor of the patient, and the defendant-physician appealed to the Supreme Court of Utah.

Although the patient alleged in his bill of complaint that he asked the defendant-physician to see only if he had wax in his ear and to remove it and that he instructed him to do nothing more, he did not testify in the course of the trial to the giving of any such instructions. Had he undertaken to direct his physician as to the kind of diagnosis to be made or the manner of making it, or as to the treatment to be given or prescribed, it is likely that his physician—or any other reputable, competent, skilful physician under like circumstances—would have declined to have anything to do with the case. Where, as in this case, a patient who finds difficulty in hearing goes to a physician to ascertain the cause and voluntarily submits to treatment by that physician with full knowledge of what the physician is doing, and acquiesces and consents to all that the physician does, he clearly by implication authorizes the physician to diagnose the case, to discover for himself the cause of his patient's disability, and to give such treatment as in the judgment of the physician is reasonably necessary. Although the patient may have believed that his disability was due to an accumulation of wax in his ear, that belief on his part did not relieve the physician of the obligation to discover the true cause of the disability that he was called on to remedy. Where one has voluntarily submitted himself to a physician for diagnosis and treatment, it will be presumed, in the absence of evidence to the contrary, that what the physician did was either expressly or by implication authorized.

The gravamen of this action, said the Supreme Court, was negligence. No attempt was made by the patient or by any other witness to explain how the plaintiff's hearing could have been or was destroyed by the use of a eustachian catheter. All that the patient said was that he had hearing in his left ear when he got into the physician's chair, that when the catheter was inserted and removed he felt a change in his hearing, and that thereafter he could not hear through that ear. This, he contended, was prima facie evidence of negligence and cast on the defendant-physician the duty of showing that such impairment of hearing as developed during treatment, if any, was not caused through his fault or neglect. Even if it were assumed, however, that that duty was cast on the defendant-physician, it was fully discharged by his showing the condition of his patient's ear when he first examined it; by showing what he did in diagnosing and treating the case; and by showing indisputably, not only by his own testimony but by that of three skilled otologists, that the instruments employed were standard, suitable and such as were generally used by skilled otologists, and that the use of them, as it was indisputably shown they were used, could not have injuriously effected the patient's hearing. All this being undisputed, the jury was not at liberty to disregard it and to render a verdict contrary to it or based on surmise or conjecture. In some cases the opinions expressed by experts are not necessarily conclusive on the jury. The jury may and is permitted to reach its own conclusion on an ultimate fact though such conclusion is adverse to the opinions expressed by the experts. In many cases involving questions of professional skill, however, with respect to which the layman has no knowledge and cannot accurately judge, the jury is not given so wide a latitude. This rule is quite generally applied in actions of malpractice, but not necessarily in all. A treatment may plainly indicate that the physician was negligent and an act shown to have been done or omitted may be such as obviously not to involve professional skill, under which circumstances the opinion of an expert as to the performance or nonperformance of the act is not required. The present case, however, does not fall within this class of exceptions. The trial court erred in refusing to grant the defendant-physician a nonsuit and refusing to direct a verdict in his favor.

The judgment of the court below was reversed and the case remanded for a new trial.

Books as Evidence: Amenities of Witness Stand

(Edwards v. Union Buffalo Mills Co. (S. C.), 159 S. E. 818; Baker v. Southern Cotton Oil Co. (S. C.), 159 S. E. 822)

The South Carolina Code of Civil Procedure, 1922, Section 744, provides that in all actions or proceedings, civil or criminal, in which the question of sanity or insanity or the administration of poison or other article destructive to life is involved and in which expert testimony might be introduced, medical or scientific works, or such parts hereof as may be relevant to the issues, shall be admissible, to be read before the court or jury, in addition to such expert testimony. The fact, says the Supreme Court of South Carolina, that the general assembly found it necessary by a special enactment to authorize the reading of medical or scientific books in cases involving insanity or the administration of poisons or other deadly articles is unanswerable proof of the assembly's intention that such books should not be read to the court or jury in other cases. Such books may be legitimately used by counsel in framing hypothetical questions, but they cannot be used as testimony.

A hearsay statement, according to Corpus Juris, does not become competent by reason of the fact that it is printed, even though it appears in the responsible form of a book, and even though such book is a treatise by an author of standard authority on a scientific subject, such as a medical treatise (22 C. J. 210, 211); nor can the admission of evidence from a medical book be secured indirectly by asking a medical expert whether extracts read to him from such a treatise are accurate statements of the facts (*Davis* v. *State*, 38 Md. 15; *Marshall* v. *Brown*, 50 Mich. 148, 15 N. W. 55); nor is it an available expedient to attempt to corroborate a medical witness by showing that a certain treatise sustains his position (*Fox* v. *Peninsula White Lead, etc., Works*, 84 Mich. 676, 48 N. W. 203; *Huffman* v. *Click*, 77 N. C. 55). ". . . the caution of the courts in admitting opinions which are not based on the observation of the particular facts of the case, the universal requirement that the testimony given to a jury should be under the sanction of an oath, and subject to the test of a cross examination, and the probability of misleading a jury by reading to them general statements to which they are hardly competent to apply the necessary qualifications and distinctions, have led to a more or less general refusal of courts to permit scientific treatises, particularly medical books, to be proved as standard books of authority and extracts therefrom to be used as opinion evidence" (11 R. C. L. 588-89).

Such a practice as having the jurors who are trying a case leave their seats and examine the plaintiff's leg, stick pins into it, etc., makes witnesses out of the jurors and is not to be commended, but in this case the court regarded it as hardly calling for a reversal of judgment. Jurors should occupy a wholly detached attitude.

In the zeal of argument, counsel may say harsh things of witnesses who have testified against his cause, and if there is evidence to support it, allowance may well be made for intemperance of language. There is no palliation, however, when counsel, without foundation in the evidence, asperses the integrity and veracity of respectable witnesses, as in the present case, by suggesting that the medical witnesses for the defendant were liars or men who had been bought, or could be bought, by the defendant's money. Uncalled for personal abuse of a witness by counsel is objectionable and will not be condoned by the court (*State* v. *Kennedy,* 143 S. C. 318, 141 S. E. 559). In an action for personal injuries it has been held to be error for counsel for plaintiff, in alluding to physicians employed by the defendant railroad company to refer to them as "hirelings" and to denounce one of them who was named Arnold as "Benedict" Arnold (*Mott* v. *Detroit, G. H. & M. Co.,* 120 Mich. 127, 79 N. W. 3).

COMING MEETINGS

Montana, Medical Association of, Miles City, July 13-14. Dr. E. G. Balsam, 208 North Broadway, Billings, Secretary.

Wyoming State Medical Society, Rock Springs, July 18-19. Dr. Earl Whedon, 50 N. Main Street, Sheridan, Secretary.

ASSOCIATION OF AMERICAN PHYSICIANS

Forty-Seventh Annual Meeting, held at Atlantic City, N. J., May 3 and 4, 1932

(Continued from page 72)

A Study of So-Called Splenic Anemia, and Banti's Syndrome

Drs. C. P. Howard and E. S. Mills, Montreal: The diseases that have been included at one time or another under the term splenic anemia are many and varied. One by one these have been recognized as separate diseases and removed from the parent stock, until at the present time there exists some doubt as to whether there is sufficient left to justify considering the disease a separate entity. Authorities are coming to regard the disease as a collection of symptoms without any histopathologic basis whatever.

During six years, from 1926 to 1931, out of a total of 9,151 medical admissions to the Montreal General Hospital, the diagnosis of splenic anemia or Banti's disease was made in 22 cases. In 14 of these cases a histopathologic study of the spleen was obtained. In the rest, no opportunity for confirming the clinical diagnosis was afforded. The proportion of males to females was 6 to 15, a reversal of the usual sex incidence, but this is hardly significant in a small series. About half of the cases occurred in the third and fourth decades. A family history of the disease was given by one patient. Only one patient showed alcoholism. Onset in 11 cases (50 per cent) was characterized by gastro-intestinal hemorrhages. Laparotomy showed cirrhosis of the liver in only 4 of these. In the other 11, anemia, weakness, fatigue and dyspnea on exertion were present. Three patients complained of pain in the splenic region. In 6 cases the symptoms had been present less than two years. In the rest, it was two years or over. All patients appeared anemic; 2 had jaundice, 3 had ascites. The spleen showed considerable variation in size. The liver was normal in 10 out of 22 cases. The blood picture was constant. Some degree of hypochromic anemia was present, but the red cell count was above 4 million in 9 cases. In sixteen cases there was leukopenia. The plasma bilirubin was increased in 11 cases. Blood platelets were reduced in 14 cases.

The observations lead one to believe that the clinical diagnosis of splenic anemia must depend on a history of unexplained gastro-intestinal hemorrhages, a chronic intractable hypochromic anemia and little but the finding of an enlarged spleen on clinical examination. The hematologic observations are diagnostic. Splenectomy was performed in 11 cases, with 3 fatalities; in the latter, all the patients had cirrhosis of the liver. None of the patients operated on, who previously had hemorrhages, have had a recurrence even after six years. Two had relapses into anemia but responded to therapy.

Dr. Rhea, our pathologist, reports that these spleens are different from cases showing ordinary portal cirrhosis. The venous sinuses of the pulp are dilated, but the pulp is not increased. The more advanced cases progress toward fibrosis. Finally, it seems that in true splenic anemia the reticulo-endothelium of the spleen undergoes physiologic and histologic changes. Removal of the spleen gives relief if it is undertaken early and before portal obstruction has occurred.

DISCUSSION

Dr. Henry A. Christian, Boston: I should like to ask whether splenic anemia and Banti's disease are regarded as synonymous terms or not. I should like to know whether in the title of this paper as published on the program it should be "and" or "or." I should like to ask whether hematopoietic activity was shown as in enlarged spleen with anemia of this type.

Dr. Walter Hamburger, Chicago: I should like to know whether the following type was included in this group: In 1920 Eppinger, from a study of his cases, drew a picture of thrombosis of the splenic vein, with enlargement of the spleen and anemia and leukopenia. This was distinct from Banti's disease, so-called, but on the basis of accessory symptoms the diagnosis can be correctly made. There are a large number of cases in the German, French and Italian literature, but there are few in the American literature. In 1904 Warfield showed extensive thrombosis of the splenic and portal veins. Warfield thought that thrombosis was the essential cause of the condition. I have found three other references. In children, removal of the spleen has seemed to have a beneficial effect.

Dr. Joseph L. Miller, Chicago: The authors said that this disturbance was in the veins coming from the stomach. Now without thrombosis why should the patients have hemorrhage?

Dr. George Blumer, New Haven, Conn.: We have two cases now at the New Haven Hospital. There is a characteristic history of the patients' having had, for several years before admission, a febrile illness and pain in the upper left quadrant of the abdomen. That sign helped to put us on the alert.

Dr. C. P. Howard, Montreal: Many will wonder at our temerity in introducing such a well worn subject. I have had interesting discussions on it with Dr. Krumbhaar. As an old student of Osler I have had a great deal of interest in splenic anemia, and in thirty years of experience I have wavered from one side to the other, and only recently have I been convinced by Dr. Rhea, my associate in pathology, that only a limited group of cases can be really named Banti's disease. The term splenic anemia is fast disappearing from our terminology. Graham's cases of hemolytic jaundice are distinct entities, but there is a small and distinct group that can correctly be called Banti's disease. Clinically we think we can recognize this group mainly by exclusion and by applying modern hematologic methods. Gordon and other workers in Montreal have applied these methods. The cases have been studied both before and after operation. Our clinical reports hinge on Dr. Rhea's pathologic diagnosis. When he says Banti's disease, we are satisfied. There are many who will dispute such a state of mind, but we shall stick to the term Banti's disease for this group of cases. Dr. Miller asks why hemorrhage should occur without thrombosis. Many cases that came to necropsy have shown varices and also dilated vasa brevia, and profuse hemorrhages have occurred, why more than with thrombosis I cannot say. I feel that there is a small group which still must be called Banti's syndrome.

Dr. Thomas McCrae, Philadelphia: Dr. Christian referred to the terminology. Drs. Howard and Mills have used the term Banti's disease. The lesion that Banti described was splenic anemia with secondary portal cirrhosis, but in certain cases the patients may die without portal cirrhosis. Should these be regarded as cases of Banti's disease? Splenic anemia was the term used before Banti's disease, but Banti's lesion included portal cirrhosis. Many of the cases that are diagnosed as Banti's disease are really syphilis of the liver. A distinction should be made between splenic anemia and Banti's disease. If the condition includes portal cirrhosis, it is really Banti's disease.

Dr. W. S. Thayer, Baltimore: Did any of these patients from whom all the spleen had been removed die later with gastric hemorrhage or hemoptysis?

Dr. E. S. Mills, Montreal: Dr. Howard has answered most of the questions. In answer to Dr. Thayer, none of the patients with gastric hemorrhage have had recurrence, and none died. In one case in which splenectomy had been performed in 1927 (a case of Banti's disease) there were extremely large vasa brevia from the spleen to the stomach. The patient was operated on later for pyloric ulcer, which was not present at the time of the splenectomy. We were interested to find that the dilated vessels were now of normal size and that the liver was normal five years after the first operation. I should have mentioned that none of the cases showed thrombosis of the splenic vein. As to the question of terminology. It should be realized that many of the cases originally described by Banti were undoubtedly syphilis. I think the preferable term to use is splenic anemia. We had one splenectomized patient who undoubtedly had syphilis, although sections of the liver at operation and the spleen did not show syphilis.

Treatment of Malignant Neutropenia with Pentose Nucleotides

Drs. Henry Jackson, Jr., Frederic Parker, Jr., F. H. L. Taylor and James Rinehart, Boston: There are a variety of ill defined clinical conditions of unknown origin that are termed leukopenia. These are accompanied by a grave prognosis. Two types may be noted: (1) the agranulocytotic angina described by Schultz and (2) the type with overwhelming sepsis. A great number of remedies have been suggested for treatment, and a few have been successful. Derivatives of nucleic acid have the power to raise the peripheral white blood cell count, just why is not clear. In 1922 one of us (Jackson) isolated pentose nucleotides from normal blood. As their presence is demonstrable in normal persons, I tried treatment of leukopenia with this substance. The treatment has been used by different physicians in different parts of the country. Intramuscular injections of 10 cc. of solution of nucleotides twice daily were given, until improvement was shown; that is, until the white blood cell count had been normal for three days. Other forms of treatment were purposely omitted. Of fifty-eight patients treated, forty-one recovered (71 per cent). In a former untreated series, we had 80 per cent mortality. The etiology in the treated series was as follows: benzene poisoning, two cases, 100 per cent recovery; sepsis cases, thirteen, with 85 per cent recovery, and agranulocytic angina, forty-three cases, with 65 per cent recovery. In one severe case of bilateral pneumonia with a leukocyte count of 200, the patient recovered. The leukocyte count begins to rise about the fifth day and is progressive thereafter. This is about the time of hematologic regeneration shown with use of liver extract.

The Treatment of Granulopenia with Nucleotide Derivatives

Drs. James S. McLester, Birmingham, Ala., and W. H. Parsons, Vicksburg, Miss.: Two patients with granulopenia were treated with the nucleotide derivative adenine sulphate. The illness of one of these was acute and stormy; that of the other, chronic and long drawn out. Both patients showed immediate and marked improvement on receiving intravenously 0.5 Gm. of the drug daily. Both recovered.

DISCUSSION

Dr. Paul Reznikoff, New York: I have studied certain cases, some of which were definite agranulocytosis. In some there was a question whether the diagnosis should be aleukemic anemia. In some, arsphenamine therapy was used. Of thirteen patients, ten recovered, or 77 per cent. Usually the response takes place within forty-eight hours in all acute cases. The second point is the use of solution of epinephrine. With two exceptions there was no reaction. The objection is that it is rather insoluble. I agree with the authors that a great many spontaneous recoveries occur. I think that three of my patients were showing a beginning recovery before epinephrine was given. In clinical work one is dealing with contradictory evidence. I think that agranulocystosis must be produced experimentally in animals before the point can be proved.

Dr. F. G. Blake, New Haven, Conn.: One point of difference is in time response as shown by Dr. Reznikoff to be forty-eight hours and by Dr. Jackson and his co-workers to be five or six days. Have the latter observed a well defined response in that time? Several patients whom I have treated are included in their response. Our initial response is forty-eight hours, at which time young granulocytes appear in the blood.

Dr. Joseph L. Miller, Chicago: Have Dr. Jackson and his co-workers noted any disturbing reaction, such as thrombophlebitis, after intramuscular injection of nuclein?

Dr. F. W. White, Boston: The significance should be realized of the contribution made by Dr. Jackson and his co-workers. If one can take a clean chemical substance made synthetically and cause a drift of differentiated cells manufactured in the bone marrow toward polynuclear cells, it is a matter of great importance. If a chemical substance of known composition can be introduced into the body when there is a lack of that substance which acts as a catalyst, a means is afforded of affecting clinical phenomena in which the lack of a certain substance is the cause of the condition. If one can succeed in adding a clean chemical substance to influence the underlying chemistry of differentiation of cells, an advance has been made toward understanding the processes that go on in the body.

Dr. Henry A. Christian, Boston: Biologic factors have an influence in this problem. There are two fundamental disturbances which precipitate this sudden calamitous development. Have these individuals a deficiency in the hematogenous apparatus? Are they abnormal in this respect always, and do they respond in an unusually violent way to some slight factor or is it a disease factor in which the cause is some virulent organism, which gets an opportunity to develop in some entirely normal individual? In other words, are we dealing with a type of general condition in familial blood disease, or are we dealing with a peculiar form of infectious disease? I had the misfortune to have such a case develop in a house officer. He apparently responded in a peculiar way to infection. He had had his tonsils removed at the Mayo Clinic. Next day he had a condition which made it doubtful whether he had scarlet fever. He was desperately ill, had a rash, and temperature of 105 F., although the lesion in the throat was only a minor infection. The terminal illness started as a streptococcal tonsillitis. There was a great drop in leukocytes. He gave little or no response to the material furnished by Dr. Jackson. He died in four days. It looks to me as if there is something fundamentally important in this disease that no one knows about. I should like to ask the readers of papers what their conception is of this condition: Is it something that occurs suddenly or is it a chronic potential disturbance made possible by a cause which would be slight in a normal individual?

Dr. Eugene S. Kilgore, San Francisco: A woman, now 62, has been observed five or six years and always has a white cell count between 1,200 and 1,800; about 50 per cent are polymorphonuclears, and all cells, both red and white, appear normal. She has passed through several mild respiratory infections without mishap. Has Dr. Jackson any experience in the treatment of such chronic leukocytopenia?

Dr. Henry Jackson, Jr., Boston: We had one patient who had had vaccine prior to this illness. We had four altogether; one had had typhoid. One boy had sore throat and received toxin-antitoxin. He had a temperature of 105 F. The illness lasted thirty-five days and the leukocyte count was 1,000 most of the time. In regard to Dr. Reznikoff's question of dosage, our own dosage is entirely empirical. Why we chose 0.7 Gm., I don't know. I think the dose should be increased. In the case to which Dr. Miller referred, the small dose produced no effect and the larger dose brought about recovery. In one case of gangrene of the arm there was the same condition. We used the larger dosage with improvement. The case cited by Dr. Kilgore was chronic. Another such case occurred in a school boy, who has to keep up a regular dosage if he wants to keep up with his work in school. If he fails with one dose he has to give up his work. The leukocytes fall below 1,000. In some cases this is a cyclic phenomenon. It is a chance whether improvement and dosage agree. Unfortunately, we have had only a few smears to study, so we have had to take evidence of clinical improvement rather than proof by smears. As to time of reaction, we have seen an occasional young polymorphonuclear cell in forty-eight hours. Dr. Miller asks if we have seen reactions. Unfortunately we have. One lot of solution of nucleotides on the market gave severe reactions, but it has been eliminated.

In regard to thrombosis following the chemical, I know the case referred to by Dr. Miller. This interesting fact emerges: As the white cell count rises, in many cases there develops rather suddenly a septic process, such as ischiorectal abscess, or empyema. The infection has been present but the clinical manifestations are not possible in the absence of white cells. An abscess cannot develop without pus. As to the cause of the disease, I do not think we can answer Dr. Christian's question as to what true agranulocytic angina is. I think it should be differentiated from the type of disease following infection.

The Treatment of Purpura Hemorrhagica

Drs. Harold W. Jones and Leandro Tocantins, Philadelphia: The title "purpura hemorrhagica" is chosen rather than "essential thrombocytopenia," which, we think, is an erroneous term. We have observed cases in common with others in which the platelets are normal and yet hemorrhagic phenomena are present. The essential feature of this disease is not platelet reduction but capillary hyperpermeability or a combination of the two. The bleeding time is the most suitable index of this disease. In a consideration of treatment, bleeding time should be taken as an index of improvement, or at least control. This study includes fifty-three patients. In a discussion of the treatment, the spontaneous cure must be given a prominent place. Ten of our patients were of this type. The acute fulminating case, whether it is primary or an acute exacerbation of the chronic, is a true emergency. Transfusion is almost a specific in these cases. Small amounts should be used, varying from 100 to 300 cc. at intervals of from one to five days. Some cases require as many as three transfusions in twenty-four hours in order to control the bleeding time. Transperitoneal transfusions are not effective. If the transfusion is not skilfully given, a reaction may occur. Large transfusions are contraindicated in most cases. A transfusion should not be left to be performed by an intern. After the patient has been brought to a safe level by the use of transfusion, focal infection should be removed and other forms of treatment instituted, such as high protein, high vitamin diet, viosterol and ultraviolet irradiation. In cases in which these methods fail, splenectomy may be resorted to. However, most of the cases respond to medical treatment. In our group only five patients received splenectomy. One death occurred. Splenectomy is not always successful. One patient, after splenectomy, failed to show the usual increase in platelets, and hemorrhagic phenomena recurred. These we have been able to control by the use of diet, viosterol, ultraviolet rays and iron. Ligation of the splenic artery has been used in thirty-four patients, two of whom have died. The spleen decreases in size. Neither necrosis nor infarct occurs. The results with this method are a little slower but just as satisfactory as with splenectomy. The operation is performed with less danger to the patient. We feel, however, that none of the treatment suggested is entirely satisfactory. The disease has much in common with pernicious anemia. Not many years ago we were discussing pernicious anemia from the same standpoint, that is, spontaneous recovery, the fact that most of the cases occurred in the spring, that many modes of treatment benefited, that splenectomy was beneficial and that transfusions helped not a few. We conclude that this disease is a deficiency disease occurring in an individual with a constitutional defect, the acute phase of which may be precipitated by some infectious process or some agent which acts in a similar manner; and we again wish to draw attention to the fact that capillary hyperpermeability and altered bleeding time are more essential features than platelet deficiency.

DISCUSSION

Dr. Augustus Wadsworth, Albany, N. Y.: I should like to know to what extent this is attributed to an infectious process. Focal infection was mentioned. I recall a case of purpura in which the focal infection was a streptococcic abscess in the kidney which had lasted for twelve years. The patient was well except for the purpura. The diagnosis was made by examination of the urine. We recovered the streptococcus and I prepared a vaccine by growing the organisms in albumin blood broth, separating the cells from the toxin. The condition cleared up under vaccine inoculations. Later the patient was operated on for abscess and stone in the kidney. This reveals the striking action of streptococcus toxin in the tissues.

Dr. W. L. Moss, Athens, Ga.: I had a case in my family in 1929. I was requested by a physician to see my sister-in-law, who had acute hemorrhagic purpura. I think the diagnosis was clear. There had been purpuric manifestations for one month. She was very ill with extensive purpura, and bleeding from the mucous membranes of the mouth, tarry stools and constant vomiting. Platelets were nearly absent. I gave a transfusion of 250 cc. intravenously. The bleeding from the mucous membranes decreased. The bleeding time came down from thirty minutes. The hemorrhagic manifestations ceased in five days. A curious mental complex developed. She was disoriented and unable to speak. There were no hemorrhages in the eyegrounds. Lumbar puncture showed red blood cells in the spinal fluid. The fluid was xanthrochromatic. I thought there had been evidence of hemorrhage into the cerebral cortex. Roentgenograms of the teeth showed two abscesses. Two teeth were extracted, removing pus. I talked with Dr. Minot about the condition and he advised liver therapy. In half a day the platelets returned. The patient went home well. Later the platelets again disappeared from the blood, but without return of symptoms. I consulted Dr. Minot again, and he said to give more and better liver therapy. However, she did not get any more liver; nevertheless the platelets returned spontaneously.

Dr. Joseph L. Miller, Chicago: Acute purpura hemorrhagica often occurs in epidemic form in the spring, about the time of acute rheumatic fever. I used to see three or four cases every spring, without rheumatic involvement. I began to use from 50 to 60 cc. of normal blood subcutaneously twice a day, and the cases cleared up promptly. I wonder whether blood given intramuscularly would not be as good as intravenously.

Dr. Henry A. Christian, Boston: I should like to know what happened to the spleen when they ligated the splenic artery.

Dr. H. W. Jones, Philadelphia: There is a striking relation between acute and chronic foci of infection in these cases. It would seem as if acute tonsillitis, erysipelas or other acute infections immediately precede the purpuric phenomena. We have tried to make a vaccine of toxins. I think it would be interesting to try this treatment. I think there is a place for this type of therapy. Removal of infectious foci, after the hemorrhagic phenomena have been controlled, is essential to prevent recurrence. The epidemic form of this disease I would call seasonal. In normal students, the reaction to the capillary test in springtime shows that there is at this time a tendency to hemorrhagic phenomena as regards capillary permeability. Dr. Christian asks what happens to the spleen after ligation. Thirty cases have been reported in the literature, with three deaths. The spleen becomes reduced in size. Thrombosis does not occur. Reduction in size is at the expense of the pulp. There are no infarcts and no bad results. The operation is easier to perform than splenectomy. Sometimes handling of the spleen starts symptoms. I do not know any form of treatment that can be called ideal. One worker has advocated antivenin of the South American type. This controls the capillary resistance. These patients have improved. Dr. Dochez worked with minute doses of moccasin venom. All remarks on treatment have to be weighed in regard to spontaneous recovery.

The Treatment of Essential Thrombocytopenic Purpura, with Notes on Forty-Four Cases in Which Splenectomy Was Performed

Dr. Herbert Z. Giffin, Rochester, Minn.: In an endeavor to determine the place of splenectomy in the treatment of hemorrhagic purpura, the following groups of cases were reviewed: forty-four cases under personal observation in which splenectomy was done, twenty-one cases not submitted to splenectomy, and twenty incipient acute cases reviewed from the literature since 1926, and not included in Spence's collection of cases reported in 1928. Cases were grouped as chronic with multiple recrudescences, and as incipient, or those seen in the primary attack. Chronic cases were divided into mild cases, cases of moderate and marked severity, and cases seen during an acute exacerbation of the chronic disease. Incipient cases were divided into mild cases, cases of moderate severity, and cases of incipient acute progressive type. The following conclusions were reached:

1. In chronic cases of hemorrhagic purpura of a mild degree of clinical severity the patients are best treated by the careful elimination of all focal infection, the administration of large doses of iron, an adequate diet, and transfusions if necessary.
2. In chronic cases of moderate or marked clinical severity, if the condition is sufficiently disabling, the patients are best treated by transfusion and splenectomy during remission; severe recurrences should not be allowed to develop in chronic types of the disease.
3. The cases seen in an acute exacerbation of chronic hemorrhagic purpura offer the greatest difficulty in the decision for or against splenectomy. Because of the fact that fundamentally the disease is one of remissions, every opportunity should be given to the patient, in an acute exacerbation with anemia, at least temporarily to improve before the advisability of splenectomy is decided on.
4. In incipient cases of short duration and mild and moderate severity the patients should be treated expectantly and by medical measures. In most of the incipient cases the patients recover spontaneously, and remain well.
5. In incipient acute progressive cases which are defined as cases of marked severity and progressive course in their primary attack, in which improvement does not occur with frequent transfusions, the patients are best treated by prompt splenectomy. In this group of cases an early accurate diagnosis and avoidance of procrastination are important.
6. Recurrences following splenectomy have been less frequent and less severe in recent years since more insistence has been placed on removal of focal infection, and subsequent reexamination for focal infection.

Hematopoietic Response in Pernicious Anemia, Following Intramuscular Injections of Gastric Juice

Drs. Roger S. Morris, Leon Schiff, George Burger and James Sherman, Cincinnati: To determine whether the normal stomach secretes a substance which, while without effect on reticulocyte response when given orally, may, when given parenterally, cause a response, we proceeded as follows: Normal, nonanemic patients were given histamine and the gastric juice was extracted by lavage. The juice was then rendered neutral to litmus, proved sterile, and injected intramuscularly, first in rabbits, later in man, without undue reaction. Intravenous injection caused, however, severe local reaction.

Next, neutralized sterile juice in amounts up to 20 cc. was given intramuscularly to a patient with pernicious anemia. The reticulocyte response was very faint. Attempts were then made to concentrate the gastric juice by evaporation to a volume of about 3 to 5 per cent. We thus secured a preparation of definite activity in procuring reticulocyte response to about 6 per cent in a patient with one million red cells. This response was far below that produced by liver extract or desiccated hog stomach. We supposed our evaporation methods had partially inactivated the substance by the heat used (38 C.) and therefore, on the advice of Dr. Cullen, we used vacuum distillation for from two to four hours, at a temperature not above 40 C.

This distilled concentrated juice was now given to patients with pernicious anemia. The equivalent of 450 cc. of juice was given to a patient with 2.1 million red cells and it produced a reticulocytosis of 17.6 per cent in thirty-six hours. Twelve days after the injection the red count and hemoglobin percentage began to increase. During the next twelve days the count increased by 1.5 million red cells and the hemoglobin by 20 per cent. It then remained stationary until further treatment was given. In a second patient a still more striking rise was obtained. The results obtained lead us to infer that there is a powerful bone marrow stimulant present in normal gastric juice, which produces reticulocyte response and also maturation of the red cells. There is a still earlier increase in red cells containing nuclear particles. There is also an increase in the white cell count and an increase in blood platelets. We are trying, at present, to obtain greater potency through refinements of method. Since pain in the gluteal muscle and buttocks has been present after injection, we are endeavoring to procure an extract which lessens and shortens this symptom.

The antianemic substance of gastric juice is thermolabile, dialyzable and exhaustible and is probably a hormone, for which we have proposed the name addisin, after Thomas Addison, who first described pernicious anemia. Evidence indicates that this may be the physiologic stimulant of bone marrow, which maintains the blood cells and hemoglobin at the normal level. It seems highly probable that the lack of addisin in gastric juice is the cause of pernicious anemia. Its administration intramuscularly has proved to be efficacious therapeutically in this disease, and it may be found to be of use in other blood dyscrasias. Its effect on cord changes in pernicious anemia has not been determined.

DISCUSSION

Dr. H. Z. Giffin, Rochester, Minn.: My associates collected gastric juice and concentrated it in vacuo from 195 cc. down to 8 cc. There was a very slight rise two days after the injection; then the reticulocytes fell back. On the eighth day they rose and on the tenth day the reticulocytes reached 21 per cent. This is the delayed type of reaction.

Dr. W. B. Castle, Boston: I think the hematopoietic response may be of use in determining whether the intrinsic factor is present in the juice. I don't feel that I am able to say why it is necessary to assume that the substance demonstrated by Dr. Morris and his co-workers is the hormone which controls function of the bone marrow. In our early work we were anxious to discriminate clearly whether we were dealing with the substance present in the gastric juice or whether the substance acted on beef muscle to produce the reaction. Was it in the gastric juice alone, was it in the beef alone or was it an interaction between the two substances? Recently we have combined 50 cc. of gastric juice with 200 Gm. of beef muscle. It was surprising that results were not obtained with small quantities of gastric juice when injected intravenously. The effect of the substance by mouth is one-fiftieth that of intramuscular injection. Therefore 1 or 2 cc. of gastric juice administered intramuscularly should give results. Four hundred cubic centimeters of gastric juice would have an equivalent of 22 liters given by mouth. The liver, placenta, brain and pancreas all have hematogenic properties, but if one gave 22,000 cc. of gastric juice by mouth, I don't know what would happen. If our factor will work neutrally when given with beef muscle, are we giving opportunity for a certain amount of juice and a certain amount of muscle to react? I should like to bring out the fact that that possibility is still left open. We have the interaction as one factor, and hematopoiesis may be one possibility. We must be able to determine by intramuscular injection of gastric juice whether it contains the intrinsic factor or not. This work strongly suggests that possibility.

Dr. J. T. Wearn, Cleveland: Why don't calves get pernicious anemia? Perhaps there is something in grass, grain or oats that prevents this. Recently a good product of pure calves' gastric juice was obtained from the fourth pouch of the stomach of the calf.

Dr. Roger S. Morris, Cincinnati: I do not know how to explain delayed reticulocyte response in the case quoted. In my experience, similar curves have not been encountered. I do not know whether I got all the points correctly from Dr. Castle. If this is a hormone, it is dialyzable and exhaustible, which militates against its being an enzyme. Whether it is the hormone or not, which is a physiologic stimulant for the bone marrow activity, we are unable to say. After a single dose given intramuscularly, we think we have got an increase in the red blood cells, leukocytes and blood platelets and this suggests that it is a bone marrow stimulus that operates to keep a balance of the bone marrow elements. We don't know why small amounts are ineffective. Apparently concentrated juice is needed. When the juice is not concentrated there is a deeper staining but no increase of reticulocytes. When we concentrate the juice we get good results. We have tried large amounts by mouth but have not been able to draw conclusions. We fed 10 liters of hog gastric juice through a duodenal tube to one patient but there was no change in reticulocytes. As to the intramuscular injection resulting in interaction between the intrinsic factor and the beef muscle, we cannot answer that. We have examined the site of injection and have found no change either gross or microscopic, although there may have been some chemical change going on. We hope to throw light on this question later. If we can obtain a product which we can give intravenously, we can rule out the muscle reaction. When we gave from 300 to 400 cc. by mouth, the reaction began on the fifth day and reached its peak on the eighth day.

Observations on Etiology and Treatment of Sprue in Porto Rico

Drs. William B. Castle, Boston, and Cornelius P. Rhoads, Springfield, Mass.: Study of 100 cases of sprue in Porto Rico, including cases in all stages of the disease, demonstrates a close relationship between this disease and addisonian pernicious anemia as to etiology and the most satisfactory methods of treatment. As has been postulated for pernicious anemia by one of us (W. B. C.), three possible mechanisms or combinations of these may be involved in the production of the "conditioned deficiency" believed to be the immediate cause of pernicious anemia. Free hydrochloric acid was demonstrated after an alcohol test meal in the gastric contents of about half the patients examined; after histamine, in about 20 per cent more. In certain cases of sprue a lack of "extrinsic factor" in the diet or a lack of "intrinsic factor" in the gastric juice, both in early and in late stages of the disease, was demonstrated. In some advanced cases an apparent difficulty in the absorption of hematopoietic substances from the gastro-intestinal tract was found to be an additional factor conditioning the major deficiency. The deficient substance is apparently identical with the hematopoietic substance produced by the interaction of beef muscle and normal human gastric juice or with the extracts of liver described by Cohn, Minot and their collaborators as effective in pernicious anemia. The sternal bone marrow examined after biopsy before treatment showed a megaloblastic proliferation comparable to that seen in pernicious anemia. No evidence of aplasia was obtained. No significant correlation between Monilia psilosis infection and sprue was observed in cultures of the stools in various types of anemia.

In nearly all the cases of sprue, prompt symptomatic relief of sore tongue and diarrhea was obtained from the administration of the liver extract effective in pernicious anemia either orally or especially by parenteral injection. The latter procedure was positively life saving in a few cases and the cost of treatment was materially less. In cases presenting a hyperchromic blood picture, adequate dosage with liver extract alone produced reticulocyte crises and improvement of the blood values occasionally as striking as in pernicious anemia but usually of a decidedly modified character. In many cases, satisfactory progress was not made without the addition of iron ammonium citrate, especially when, after treatment with liver extract, the hyperchromic anemia became hypochromic in character. In a small number of cases of sprue with an original hypochromic blood picture, iron therapy was effective in relieving the anemia but not the gastro-intestinal symptoms, which, however, yielded promptly to liver extract. In a few cases, autolyzed yeast preparations produced reticulocyte crises and improvement of the blood values.

DISCUSSION

Dr. Joseph H. Pratt, Boston: One comes across few cases of sprue in practice. In my cases I made a study of the absorption of fat. The authors have not mentioned one feature which distinguishes sprue from pernicious anemia, and that is the presence of a fatty diarrhea, which does not occur in any other condition except advanced pancreatic diarrhea. I should like to ask Drs. Castle and Rhoads if such stools were reported by them. There is an enormous amount of fat in the stools, and absorption studies show that 50 per cent of the fat is not absorbed. This condition is not observed in pernicious anemia. The authors said that within five days the diarrhea had ceased. Can they give any opinion on that point and was there any investigation made on the amount of fat in the stools? In my first case of sprue the patient had come from Porto Rico, and examination showed 50 per cent of fat in the feces.

Dr. W. B. Castle, Boston: I remember that the question was frequently asked what the difference is between sprue and pernicious anemia. It was embarrassing to realize that it could not be stated definitely in any one case. They are hard to distinguish, and yet the symptomatology is different. I have seen a case of sprue with fatty diarrhea, and yet when the patient arrived in Boston he apparently had pernicious anemia. Dr. Peabody also saw that patient, who had come from China. However, in cases like these, the sea voyage seems to cause a change. Probably the diet influences the nature of the stools. We were told that fat would produce diarrhea in these patients. We had difficulty in getting the doctors to allow us to keep the patient on a rice diet. We saw no fat in the stools, but I suspect that if the patient had eaten fat, it would have come through in the stools as there is a difficulty of absorption of some substances. But no matter what diet we gave, the administration of sufficient liver extract made the stools normal. Another piece of evidence was the clearing up of inflamed tongues. This proves the powerful effect of the substance on the lower gastro-intestinal tract and on the abnormal motility and absorption.

Chronic Severe Asthma: A Study of a Group of Cases Requiring Hospital Treatment

Dr. Francis M. Rackemann, Boston: This paper will appear in full in The Journal.

Pneumonoconiosis: An Unusually Malignant Form

Dr. Eugene S. Kilgore, San Francisco: This paper will appear in full in The Journal.

DISCUSSION

Dr. J. H. Means, Boston: I saw the first patient mentioned in this presentation. The symptoms were marked. The lungs at necropsy showed an unusual state of fibrosis. They were full of areas of emphysema and were covered with air blebs. I think it is a good thing that mention has been made of the combination of silicon and alkali. This seems to produce a silicosis with more sudden and rapid symptoms. We should be on the lookout for cases with this particular symptomatology.

Dr. Eugene S. Kilgore, San Francisco: The unfortunate thing about this preparation is that the powder is extremely fine, and this accounts for its action on the respiratory tract. The British writers think that the added alkali is responsible for the deleterious action. They offer a chemical explanation favoring the view that silica is injurious when dissolved in faintly alkaline body juice, and that when alkali is introduced this effect occurs very rapidly.

The Mechanism of Nonobstructive Emphysema

Drs. Harry L. Alexander and W. B. Kountz, St. Louis: There are two types of emphysema: (1) the type associated with bronchial obstruction, resulting in large lung, and (2) the senile type. Both have the barrel-shaped chest and hyperresonance of the lung. Obstructive emphysema pushes down the diaphragm so far that it has little excursion. The senile type, however, does not push the diaphragm down. If a pneumograph is put around the chest and abdomen the upper chest does the work, but in the senile type of emphysema the diaphragm does most of the work. In the obstructive type the vital capacity of the individual is reduced, but in the senile type there is little difference in the vital capacity. In the obstructive type there is considerable anoxemia and bowed spine, while the senile type shows the stiff, straight spine. There is a lesion of the intervertebral disks, and as the disks swell they crowd the bodies of the vertebrae, the spine curves and pushes away from the sternum and the ribs spread. Thus the obstructive type is primarily a pulmonary lesion, while the senile type is due to distortion of the spine, which distorts the chest wall. The senile type therefore is due to the distortion in the spine itself.

DISCUSSION

Dr. Francis Rackemann, Boston: Four out of thirteen of our cases showed emphysema. It occurred in the types of individuals that the authors have described.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Relation of Lymphatics to Thrombophlebitis.—Homans calls attention to the fact that there are forms of thrombophlebitis dependent on an unhealthy state of the vein's wall—the varicose type—and peculiar sorts, partly of local origin and partly due, perhaps, to an abnormality of the blood—phlebitis migrans. There are also venous thromboses of traumatic origin. But thrombophlebitis which affects the previously healthy veins draining the lower limbs, particularly the familiar scourge phlegmasia alba dolens, appears to be secondary to a nonsuppurative lymphangitis, which from its situation is able to attack artery as well as vein. And the principal manifestations of such a disease are neither venous nor arterial but lymphatic.

Opening Snap in Mitral Stenosis.—According to Margolies and Wolferth, the opening snap (claquement d'ouverture de la mitrale) can be heard and recorded in more than half the cases of mitral stenosis. It has not been observed in the absence of mitral stenosis. It is one of the most important diagnostic signs of this valvular lesion. The chief characteristics of the opening snap are the following: 1. The sound is a sharp snap or click. 2. It has been found to occur from 0.03 to 0.19 second after the beginning of the second sound, the ordinary range being from 0.06 to 0.11 second. 3. It is usually loudest in the fourth left interspace, occasionally in the third, slightly above and to the right of the area in which the diastolic murmur is best heard. 4. It precedes the onset of the murmur by a short interval. 5. It is usually best elicited with the patient in the recumbent position. 6. In some cases it can be brought out by exercise and by increase of the cardiac rate. 7. It tends to be louder when the rate is rapid. The interval between the second heart sound and the opening snap is influenced by the cardiac rate, tending to become shorter as the rate increases. Variations in the duration of this interval occur during auricular fibrillation and sinus arrhythmia, depending on the length of the preceding heart cycle. The opening snap is easily differentiated from reduplication of the second sound, protodiastolic gallop sound, the physiologic third heart sound and systolic clicking sounds. The time relations of the opening snap, as observed from comparisons of sound tracings with electrocardiograms, apex cardiograms, jugular phlebograms, and auricular and ventricular roentgen kymograms, exclude auricular contraction, ventricular rotation or filling, or shocklike waves transmitted from the aortic to the mitral valve, as factors in its production. All the evidence thus far available is in accord with the hypothesis that the sound is produced by the sudden limitation of the opening movement of a stenosed mitral valve which occurs in early diastole as soon as the left ventricle relaxes sufficiently to permit the pressure of the auricular blood column to become effective.

Premature Beats from Direct Stimulation of Ventricles.—Premature contractions evoked by electrical stimulation of one spot on the right ventricle and one on the left ventricle of a partially exposed human heart were recorded by Marvin and Oughterson in the three standard leads of the electrocardiogram. These were not taken simultaneously but consecutively. The authors were able to confirm the observations of Barker, Macleod and Alexander, who first showed that premature contractions derived from stimulation of the right ventricle have the chief initial deflection upward in lead I, while those from stimulation of the left ventricle have the chief initial deflection downward in lead I.

Auricular Flutter and Fibrillation.—Hamburger and his associates report an unusual case in which the auriculoventricular block accompanying auricular flutter and coarse auricular fibrillation varied markedly during Cheyne-Stokes breathing, in one instance leading to a complete auriculoventricular block during the hyperpneic stage. Hyperpnea in this case increased the auriculoventricular block and apnea decreased it, without any apparent effect on the rate of flutter or fibrillation of the auricles.

Experimental Bundle-Branch Block.—Roberts and his associates performed experiments on cats in which either the right or left division of the bundle of His was cut. Both concordant and discordant curves were obtained. When the right division was transected, the chief initial deflection in lead I was downward in both types, but in lead III it was upward in the discordant type and the reverse in the concordant. When the left division was cut, exactly opposite results were found. In analyzing the curves, the important lead to study in order to decide on the location of the lesion appeared to be lead I.

Nasal Cavity and Direction of Fluid by Ciliary Movement in Macacus Rhesus (Desm.). A. M. Lucas, St. Louis.—p. 141.

Effect of Roentgen Rays on Pregnancy.—Pencharz and Long drew one ovary in each of twenty-four rats through a dorsal incision and exposed it to roentgen rays while all the rest of the body was completely protected. During pregnancy immediately following, the untreated ovary was removed. Abortion or resorption resulted in twenty-three out of the twenty-four cases. In the twenty-fourth case the normal ovary was removed so late in gestation (nineteenth day) as to make the case comparable to ordinary late ovariectomy. The irradiated ovaries contained what is apparently luteal tissue, interstitial tissue, and degenerate follicles. The presence of an irradiated ovary containing these structures is not sufficient to maintain pregnancy.

Gonad Hormone Functions.—Moore and Price describe experiments from which they conclude that a large number of reproductive phenomena, gonadal and reproductive accessory behaviors, can be interpreted logically on a basis of hypophysis-gonadal interrelationships. Gonads function only when they are forcibly stimulated by certain secretions that are normally provided by hypophyseal activity. The activity of the hypophysis, on the other hand, is to some extent controlled by gonadal secretions, for when these gonad hormones are present in effective amounts hypophyseal activity is lowered. Sex-hormone antagonism, in the Steinach sense, does not exist. Injuries to the gonads follow administration of either sex hormone into either sex, and the authors interpret the mechanism as a hypophyseal involvement.

Cowper's Gland and Its Reaction to Castration.—According to Heller, Cowper's gland of guinea-pigs and rats undergoes involution after castration, the changes occurring more rapidly in the rat. These glands reach their adult secretory state at approximately 55 days of age in the rat. Castration atrophy in Cowper's gland is detectable in the rat in ten days; it is well advanced at twenty days, and reaches essentially its maximal state of involution at approximately a hundred days. Injection of testis hormone prevents castration atrophy or repairs castration damage already present. Administration of gonadal-stimulating substances by means of fresh hypophyseal implants or hebin injections in normal young males results in a precocious development of these glands. Administration of estrin to castrated males is without effect on Cowper's gland; injection into normal males, however, is followed by involution changes in these glands that resemble castration atrophy in all respects. Mixtures of estrin and testis hormone injected into normal or castrated males result in normal Cowper's glands. Estrin injections into normal males accompanied by administrations of gonadal-stimulating substances do not cause damage to Cowper's gland. These observations are in agreement with the factual basis of the theory of a reciprocal influence between gonads and hypophysis, developed by Moore and Price, and are interpreted on that basis.

Agranulocytosis: Report of Case, with Autopsy Observations. L. W. Empey and F. Proescher, San Jose, Calif.—p. 947.

Pulmonary Diseases.—Stewart's report is based on a study of 5,816 children, including 3,981 (68.4 per cent) and 1,835 (31.6 per cent) children having negative and positive Pirquet tests, respectively. In 1,179 children, or 20.3 per cent of the entire group of 5,816 persons, intrathoracic disease was revealed by roentgen examination. The prevailing type of lesion found in these 1,179 children was that produced by the first infection by Mycobacterium tuberculosis, as shown by the fact that childhood tuberculosis was found in 82.3 per cent (970 instances) of these cases. For the 3,981 children having a negative Pirquet test, intrathoracic disease was reported in only 6.4 per cent of the cases (255 children), of which 3.9 per cent (154 cases) had lesions characteristic of the childhood type of tuberculosis. If questionable and slight intrathoracic glandular calcifications are excluded, the data show that the more conspicuous lesions characteristic of childhood primary tuberculosis were found in only 0.58 per cent (23 cases) of the children with a negative Pirquet test. For the 1,835 children having a positive Pirquet test, intrathoracic disease was discovered by roentgen examination in 50.4 per cent (924 cases), and 44.5 per cent (816 children) had lesions of the childhood type of tuberculosis. When questionable and slight intrathoracic glandular calcifications are excluded, the more conspicuous and readily identified lesions typical of tuberculosis of first infection were found in 25.9 per cent (475 cases) of the 1,835 children with a positive Pirquet test. If a value of 100 per cent is assigned to the Pirquet test as measuring its efficiency in the discovery of childhood tuberculosis, the roentgen examination has a reliable efficiency of about 25 per cent, and the physical examination an efficiency of a small fraction of 1 per cent. From the standpoint of the appearance of lesions discovered by roentgen examination, childhood pulmonary tuberculosis of first infection may be divided into the following three types: (1) resolving pneumonic-appearing parenchymal consolidations, which represent early stages of the disease; (2) intrathoracic glandular calcifications of various degrees, which represent late permanent stages of the disease, and (3) Ghon tubercules associated with hilar gland calcification, which represent late and permanent stages of the diseases. These various types of lesions merely represent various developmental stages in the evolution of the disease produced by a primary tuberculous infection, between which many transitional stages may be noted. The end-result in nonfatal cases is always the same in that calcification of the hilus glands appears, or that Ghon tubercles develop associated with calcification of the homolateral hilus lymph nodes.

Human Milk Studies.—*Nims and her associates studied the variations that occur in the composition of human milk at periodic four hour intervals throughout the day and night. The subjects were three women living in their usual home environments, typical of the average middle-class American family. Under the conditions of the experiments it was demonstrated that, independently of variations in such factors as food, rest, activity, stage of lactation, climate and possible errors involved in the methods followed, there were significant changes during the day in the volume of the breast milk of the three women, and characteristic daily trends in the variation in composition of the milk with respect to the fat, total solids, total nitrogen, total ash, calcium, phosphorus and chloride components.*

Respiratory Metabolism in Infancy and Childhood.—Wyatt and his associates briefly summarize the results of their study of the effect of thyroid therapy on the energy exchange of normal infants as follows: 1. Thyroid extracts, in adequate dosage, exert a calorifacient action in infants with apparently normal thyroids and often induce in these subjects clinical symptoms characteristic of spontaneous hyperthyroidism. 2. The metabolic response of these subjects to thyroid extracts in smaller dosage is inconstant. 3. The minimal amounts of the drug capable of producing profound clinical and metabolic reactions in infants without hypothyroidism are apparently comparable to the dosage required to induce a similar response in adults without hypothyroidism. They notably exceed the usual dosage effective in subjects of all ages with hypothyroidism. 4. The usual persistence of thyroid action in these normal infants was approximately two to three weeks. This time interval coincides with the usual duration of thyroid action reported for normal adults and is considerably shorter than the persistence of such action in subjects with hypothyroidism. 5. In terms of absolute dosage, the whole gland product and the desiccated extract vary markedly in their potency as calorigenic agents, but they are equally potent when judged by their iodine content. On the latter basis, thyroxine, the active principle of the thyroid hormone, appears to be the most potent calorigenically of the three products.

Hymenolepis Nana.—*Tsuchiya and Rohlfing describe two* cases of hymenolepis infection (Hymenolepis nana) in St. Louis, in addition to those previously reported by Goldman. Neither clinical nor laboratory observations, however, were indicative of pathologic conditions in these children. With a view to determining the possible source of hymenolepis infection, a cross-infection experiment with ova from human sources was carried out in rats. The results of this study showed that two of six clean rats were successfully infected with Hymenolepis nana. Subsequent experiments showed that five of ten clean rats were found to be infected with the ova of the two rats previously infected with human materials. Since there is the possibility of acclimatizing human parasites in rats, rats in turn may become one of the sources of the infection in human beings.

Influenzal Meningitis.—Five patients with acute meningitis caused by the influenza bacillus were treated locally by Ward and Fothergill with the injection of fresh normal serum and an efficient specific antiserum. All the patients died eventually, but in every case the cerebrospinal fluid was sterilized for varying periods, up to fourteen days. The authors believe that the cause of death was almost certainly due to a localization of the inflammatory process in areas that were shut off from the general subarachnoid space, and so protected from the action of the complement and the specific antiserum.

Blood Cholesterol.—Leopold and his associates report that ultraviolet irradiation increased the blood lipids in 25 per cent of thirty-two patients studied. Treatment by inunction with nonirradiated wool fat produced no changes in blood lipids, but subsequent treatment with irradiated wool fat definitely increased the lipid fractions of the blood. Treatment with inunctions of wool fat followed by ultraviolet irradiation produced significant increases in blood lipids in 89 per cent of the cases with a low initial cholesterol and in 33 per cent of the cases with a normal initial cholesterol. Treatment with wool fat and ultraviolet rays also produced a rise in free cholesterol and cholesterol esters in 86 per cent of the cases, and of the total alcohol ether extract in 91 per cent of the cases in which this treatment was given. Of ten cases in which a low initial value for lipoid phosphorus was encountered, none showed a rise in lipoid phosphorus after treatment with wool fat and ultraviolet irradiation. Low values for cholesterol are an indication as to the necessity for treatment with inunctions of wool fat and ultraviolet irradiation. Changes in the amount of cholesterol serve as a guide to the amount of treatment to be given.

Pneumonia and Tuberculosis Among Miners.—In a study of 2,603 cases of pneumonia and 238 deaths from tuberculosis among surface workers and miners Kibbey noted that the annual case incidence of pneumonia for ore miners was nearly double that for any other group; surface workers came next, and of all wage earners coal miners suffered least. The story of pneumonia deaths presented an entirely different picture. The fatality rate expressed in deaths per hundred cases was found to be considerably higher for surface workers; 560 cases with 166 deaths, a rate of 29.6; ore miners 143 cases with 33 deaths, rate 23.0; coal miners 127 cases with 29 deaths, rate 22.8; female dependents 994 cases with 180 deaths, rate 18.1; male dependents 779 cases with 102 deaths, rate 13.1. Practically 100 per cent of the coal miners who formed the basis for this investigation have anthracosis, but their pneumonia incidence rate was exactly in proportion to their number in the entire population. A rate of 4.6 cases per thousand, the lowest of any wage earning group, compares quite favorably with 4.3 cases per thousand dependents, which includes all women and children. The fact that coal miners exhibited the lowest pneumonia fatality of any wage earning group would appear to indicate that anthracosis has had no influence either as a predisposing factor or in contributing to fatality. In the operations in which the men worked, several ore mine openings constitute a single operation. Each operation is provided with a large centrally located bath house at which men do their changing. These houses are constantly at temperatures around 80 F., and many of the miners must walk half a mile or more from mine to bath house. Coming from the mine as they do, in clothing dampened with perspiration, they are in certain weather subjected to considerable chilling before reaching a bath house which is kept too hot. Leaving an excessively heated bath house, they are subjected to a second chilling on the walk home or car line, which may be a mile distant. The author believes that these facts more nearly account for the prevalence of pneumonia among ore miners than any condition under which they work, or the presence of possible pneumonoconiosis. The fact that this particular group is more resistant to the destructive processes of pneumonia than are those in whom pneumonoconiosis is absent would appear to argue the soundness of such reasoning. Although coal miners presented the lowest pneumonia fatality rate of any wage earning group, the author's experience is that coal miners die from tuberculosis with nearly three times the frequency of the average for total population and have a mortality rate more than two and a half times that of surface workers. Expressed in deaths per thousand persons annually, the rates are: coal miners, 1.28; ore miners, 1.14; surface workers, 0.46; total population average, 0.44; dependents, 0.36. That the etiology of tuberculosis is in some way intimately bound up with calcium metabolism appears to be reasonably certain. Calcium metabolism, regardless of diet, is impossible in the absence of sunlight. The author tentatively suggests that high death rates from tuberculosis among ore and coal miners might more reasonably be attributed to their deprivation of sunshine than to a condition which apparently does not influence other respiratory diseases.

Tuberculosis in Young Females.—Deacon presents the results of a study of the occupation of young females dying from tuberculosis. During the years 1927, 1928, 1929 and 1930 there were in Michigan 2,630 deaths of females between 15 and 29 due to tuberculosis (all forms). The death certificates of 289 did not contain a statement of occupation, or the statement was too ambiguous to enable one to determine whether or not the person was gainfully employed. These 289 were therefore eliminated and only the 2,341 in which the statement of occupation was fairly clear were considered. The occupations given were: school, 14.1 per cent, and home, 62.3 per cent—not gainfully employed; industry, 23.6 per cent—gainfully employed. Of the 2,341 deaths, 1,787, or 76.4 per cent, were indicated as not gainfully employed; 554, or 23.6 per cent, were gainfully employed. From this showing it is obvious that industrialization is not an important factor in the mortality from tuberculosis among young women. The author sees no reason to believe that there is any more hazard involved when a young woman leaves her home, whether she goes to school or into an office, in most cases working not to exceed eight hours under favorable sanitary environment. Whether one considers housewives, employed persons or students, the problem is in the home; and every one who has experience in public health work realizes that this is the most difficult group to reach.

Moniliasis and Moniliids.—According to Hopkins, the evidence accumulated by many investigators indicates that organisms related to yeasts are the cause of a number of common dermatoses. Recent studies show that at least a majority of these are caused by one well defined species, Monilia albicans. This is the same species that has been found in thrush of the mouth and in intestinal sprue. The more common skin lesions, interdigital erosion, paronychia and perlèche, are so frequently associated that they apparently constitute one disease, moniliasis of the skin. The intertriginous forms and the vulvitis occur chiefly in diabetes. The fact that patients with moniliasis of the skin harbor the parasite in their alimentary tracts suggests that this focus is a factor in the occurrence and persistence of the skin lesions. Sensitization to Monilia albicans occurs. In a few cases the conclusion seems justified that skin lesions in sensitized persons result from absorption of substances produced by monilias in the alimentary tract or by some other focus of infection. Further study is necessary to determine whether such sensitization to alimentary infection is a frequent or an important factor in the causation of dermatoses.

Occupational Melanosis.—Wieder directs attention to a group of industrial dermatoses in which melanosis is an important feature and which heretofore has received little consideration in the American literature. The rôle of coal tar and petroleum derivatives possessing photodynamic activity as etiologic factors in these cases is reviewed. A case is described in which a benzanthrone-anthraquinone compound and naphthalene containing only a minute trace of an impurity of unknown chemical formula were incriminated as etiologic factors by means of skin tests.

Superficial Glossitis and Perlèche.—Robinson and Moss report a series of twenty-two cases of perlèche in adults, which were complicated by superficial glossitis in six cases, by erosio interdigitalis in eight cases, by paronychia in eight cases, and by dermatitis of the toes in four cases. A superficial glossitis from which Monilia albicans can be isolated occurs sometimes in association with perlèche and sometimes independently. Monilia albicans was recovered from perlèche lesions in thirteen cases and from a number of the complicating mycotic lesions. The authors consider that it is doubtful whether the other species of yeastlike organisms obtained were the cause of the lesion from which they were isolated.

Dermatoses Associated with Neurocirculatory Instability.—Becker presents impressions as obtained from the study of 204 unselected cases of generalized and localized pruritus, neurodermatitis, dyshidrosis, urticaria, angioneurotic edema, neurotic excoriations and alopecia areata. The conditions mentioned seem to be found only in a certain type of person, with the exception of some cases of urticaria. The underlying constitutional background seems to be hereditary but not familial. Many of the patients fall into the so-called neurasthenic groups, with the picture of general asthenia and neurocirculatory instability. The constitutional symptoms are easy fatigability, nervous and mental irritability or depression, hyperkinesia, functional gastro-intestinal disturbances, headache, backache, vasomotor rhinitis and asthma. The combinations of dermatoses in the same person are first angioneurotic edema and urticaria, and opposed various combinations of the others. Therapeutic considerations consist, first, in the removal of the precipitating factors; secondly, in the correction of the underlying irritability and exhaustion, and, thirdly, in palliative therapy. Children should be carefully controlled in order to prevent serious difficulty later in life. The prognosis is better if the dermatosis appears late in life. Cooperation of the patient is a necessary aid to therapy. Without this cooperation, palliative therapy is only temporarily efficacious. From the evidence obtained, it would seem that this group of dermatoses should be given a place in the classification of functional nervous disorders. The author believes that the designation "neurodermatoses" might well be applied to them.

Head Injuries: Encephalographic Observations.—As a result of his studies, Friedman has been led to revise his conception of the so-called traumatic neuroses following serious injury to the skull. On the basis of accumulating experience, one may say that, at least in some of the cases of "traumatic neurosis," definite organic changes that can be visualized in the encephalogram have been brought to light. In this field of medicine, in which diagnosis is frequently difficult, it becomes the duty of the clinician to employ every means at his command in order to arrive at a correct interpretation of the patient's symptom complex. Encephalography offers a valuable means of differentiating between organic and functional syndromes.

Differential Diagnosis of Tumor of Brain.—Grant presents five cases of malignant hypertension. In every instance headache, vomiting and choked disk were noted. In none of the cases at the first examination was sufficient evidence of renal disease shown to force consideration of nephritis as the underlying cause of the hypertension. Three of the patients were too young to make generalized arteriosclerosis seem probable, and only one of the three showed definite evidence of hardening of the peripheral vessels. In the two other subjects, rigidity and pulsation of the temporal, brachial and radial arteries were noted. Two of these young persons without sclerotic peripheral vessels showed such definite neurologic evidence of a cerebral lesion, coupled with papilledema and increased intracranial tension on lumbar puncture, that a diagnosis of tumor of the brain was made. Surgical exploration failed to reveal a tumor. Furthermore, the decompression left at the operation failed to reduce the papilledema, although in one case the headache was relieved. All the patients died within six months after discharge from the hospital, an evidence of the serious prognostic import of papilledema in hypertension.

Intracranial Tumor.—According to Gibbs, in cases of tumor of the brain with unequal choked disk greater choking tends to occur on the same side as the tumor. The incidence of homolaterally greater choking is highest among tumors of the temporal and parietal lobes. The incidence of contralaterally greater choking is highest among occipital tumors. The incidence of homolaterally greater choking is higher among cases of parietal tumor with low grade choked disk than among similar cases with high grade choked disk. The incidence of homolaterally greater choking is lower among cases of occipital tumor with low grade choked disk than among similar cases with high grade choked disk. There is no significant association between the side of greater choking and the side of greater involvement of the third to the seventh cranial nerves.

Amyotrophic Lateral Sclerosis with Mental Symptoms.—Wechsler and Davison call attention to the fact that, in the vast majority of recorded cases, amyotrophic lateral sclerosis is not characterized clinically by definite psychotic manifestations. Most of the cases with such manifestations reported in the literature can better be explained by an incidental association with schizophrenic, manic-depressive or paranoid syndromes or with simple depressions. In older patients the occurrence of definite organic dementia could with more reason be ascribed to the coexistent, but at the same time independent, general cerebral arteriosclerosis. In six cases observed by the authors and very few others the psychosis apparently was the cerebral expression of one generalized pathologic process.

Syphilis of Nervous System.—Winkelman and Eckel report seven unusual cases of syphilitic involvement of the central nervous system. Three cases of gumma are included. In all the process began as a focal meningitis with secondary invasion of the parenchyma. Cerebral syphilis and dementia paralytica may be combined in the same case, as in a case that terminated as juvenile dementia paralytica. Serologic examinations were negative in two cases, both of the vascular type, one of the brain and one of the cord. The authors emphasize the fact that cerebral syphilis and a toxemia of any sort may produce severe cortical endarteritic changes in the small blood vessels which are indistinguishable from one another.

Chronic Progressive Chorea.—Davison and his associates present three cases of chronic progressive chorea: one of Huntington's type, one of questionable Huntington's type and one arteriosclerotic. Histopathologically, all showed cortical and neostriatal changes. Two of the cases also showed cerebellar changes. The authors made an attempt to interpret the mechanism of chorea on a corticostriatal basis.

Tumor of Metacarpal Bone.—Jaffe and Mayer describe an osteoid tissue-forming tumor of a metacarpal that began in a girl, aged 12 years. At first the tumor grew slowly. A biopsy was performed, the histologic sections showing osteoid tissue and numerous osteoblasts. The growth was slow for about the next two years, when it became very rapid. After growing rapidly for about six months, an encapsulated mass measuring 10 by 6.5 by 6 cm. was removed from the hand; section showed almost complete destruction of the metacarpal bone. The peculiar feature of this osteoblastic tumor was its capacity to produce large amounts of osteoid tissue, much of which was free from calcium. The tumor had some features common to osteogenic sarcoma but showed a complete absence of cartilage or cartilaginous elements in numerous sections. It was especially characterized by homogeneity of the histologic picture, a lack of polymorphism of the cells, and an absence of tumor giant cells. There has been no recurrence one and a half years after extirpation. The patient has gained 25 pounds (11.3 Kg.) and has remained free from metastases for over four years after the original biopsy, in March, 1927. The authors believe that the case demonstrates an instance of so-called osteoid chondroma of Virchow, which is an osteoid tissue-producing tumor, the prognosis of which is better than that of osteogenic sarcoma. It is their belief that, had extirpation of the metacarpal bone been delayed much longer, the tumor probably would have undergone biologic transformation and developed the malignant capacities of true osteogenic sarcoma.

Activity of Isolated Intestinal Segments.—Puestow isolated various segments of bowel from the intestinal tract and transplanted them onto the abdomen. It was observed that feeding stimulated an increase of muscular and secretory activity and hyperemia of these segments. Because food did not come in contact with the segments, the stimulus must have been carried by nervous or vascular pathways. Following division of all extrinsic nerves to these intestinal transplants, the response to food could not be clearly demonstrated. This suggested that the increased activity after feeding was at least partially due to extrinsic nervous control. Electrograms made of these various isolated segments of intestine revealed a characteristic curve of altered potential. They also showed a constant rate for a given segment under most conditions studied. The rate was most rapid in duodenal segments, less in jejunal segments and slowest in segments of the lower part of the ileum. Peritonitis and ether anesthesia were found to diminish this rate moderately.

Concretio Cordis.—Bigger considers decortication of the heart a formidable operation but one that is distinctly indicated for the relief of concretio cordis, which without surgical intervention is hopeless. The mortality rate is high and will of necessity continue to be so, but with improved operative technic one of the chief dangers, rupture of the heart, should be greatly diminished. If a satisfactory two-stage operation can be developed, the incidence of postoperative dilatation of the heart should be decreased.

Squamous Cell Carcinoma of Kidney.—Rabinovitch describes a case of squamous cell carcinoma of the kidney. The most interesting features of the case were the invasion of the renal artery by the tumor and the occlusion of its lumen. This resulted in complete infarction of the kidney. Similar instances of total occlusion of the renal artery by a cancerous thrombus have not heretofore been reported in the literature. This observation renders the case, therefore, unique. The various phases of cell metaplasia are discussed.

Spinal Fluid Pressure.—Milles and Hurwitz describe experiments in which they demonstrated that the reduction of cerebrospinal fluid pressure with single doses of hypertonic salt solution and dextrose is transient. A secondary rise occurs which reaches a point much higher than the original level. High concentrations of sodium chloride are definitely toxic. In view of these facts, it is probable that recurrent pressure symptoms and the occasional deaths reported are due to the secondary rise in spinal fluid pressure.

Transphrenic Spread of Diseases.—Groseclose and Swineford report six cases of transphrenic spread of disease. In only one case did the process originate above the diaphragm. In each of the other cases the primary lesion was in the abdomen, and transphrenic spread occurred directly from the under surface of the diaphragm, which was secondarily involved by cancer once, by acute hemorrhagic pancreatitis once, by tuberculosis once and by pyogenic infections twice. The spread was from the left subphrenic region to the left pleura in three cases, from the right subphrenic region to the right pleura in one case, from the right subphrenic region to both pleurae in one case, and from both pleurae and the pericardium to the region of the tail of the pancreas in one case. In one case the spread seemed to be quantitatively much greater on the right than on the left. Oddly enough, in half of the group of cases the transphenic spread occurred only on the left. Of the five pathways described by Lemon, Higgins and Graham by which lymph drains from the diaphragm, the sternal route was apparently illustrated once, the pulmonary route twice, and the fifth route, leading to the peripancreatic region, once. Simple spread from peritoneum to pleura occurred five times. The authors emphasize the importance of being mindful of the probability of transphrenic spread of intrathoracic or intra-abdominal disease. In order to anticipate some of the seemingly bizarre locations of the secondary transphrenic lesions, it is necessary to know the various routes by which materials reaching the rich diaphragmatic lymphatic plexus are transported to the blood stream.

Fractures of Knee.—According to Cary, "bumper fractures of the knee" is the term applied to designate a complex lesion occurring when a person is struck by an automobile bumper or otherwise with sufficient force to produce a comminuted fracture of the head of the fibula, a fracture of the external tuberosity of the tibia with an avulsion of the tibiofibular joint and a rupture of the external lateral ligament of the knee joint. He emphasizes the fact that in this condition complete reduction is just as essential for a stable joint with good function as is a complete reduction of a Colles' or Pott's fracture. A method of treatment is outlined which he has found highly satisfactory to date. No special skill is required to obtain reduction. Caution is directed to a careful consideration of the peroneal nerve and to avoid rough pounding. With this method the period of disability has been reduced to half the usual time required, and permanent disabilities have been greatly reduced.

Ruptured Bladder.—Martin describes a method of diagnosis of ruptured bladder which has proved so reliable that he recommends its trial. The steps in the procedure are as follows: The patient should have an opportunity to void urine. The urine, if voided, should be examined microscopically for blood. If the patient is unable to void, a catheter is passed and the bladder urine is drawn off. If a catheter cannot be passed, a urethrogram should be taken to demonstrate the nature of the urethral complication or injury. The bladder should then be filled with sterile 5 per cent sodium iodide solution that has been boiled. The bladder should be filled to the point of discomfort, or, if this sensation is not reached, one stops at 300 cc., the amount injected having been carefully noted. A roentgenogram should then be taken, the patient being so placed that the entire bladder outline is shown on the plate. The sodium iodide solution should then be permitted to drain out of the bladder without any pressure being exerted, after which another picture should be taken. Air may be injected now in order to get a contrast cystogram. This will show the amount and location of any of the extravasated mediums, and thus another bit of evidence will be obtained. When the films are developed, one will either see the regular line of a normal bladder or a distorted, indistinct picture with extravasated iodide helping to outline the ruptured bladder.

Prevention of Nutritional Anemia.—Orten and his associates describe experiments in which they demonstrated that inorganic iron fails to prevent the development of a nutritional anemia in the rat on a milk diet, whereas iron supplemented by copper permits the maintenance of an approximately normal hemoglobin level. Iron supplemented by manganese fails to prevent the development of nutritional anemia. A mixture of manganese, cobalt, nickel and zinc, supplementing iron, does not have a prophylactic action in nutritional anemia, while the same mixture plus copper prevents a decrease in the hemoglobin level. Evidence of any significant toxic effect of manganese, cobalt, nickel or zinc was not observed. Of all the metals studied, copper alone has the ability to supplement iron in preventing the nutritional anemia of the rat.

Mucoprotein as Normal Constituent of Gastric Juice.—Webster and Komarov believe sufficient data have been advanced to establish the presence in the freshly secreted gastric juice of a protein exhibiting the general properties of a mucoprotein. The striking similarity in the elementary composition of different samples obtained from several animals and its variance from that of the mucus of the surface epithelium point to this being a *sui generis* chemical body, secreted by the cells of the gastric glands themselves.

Unsaturated Fatty Acids in Diet.—Evans and Lepkovsky confirm the fact that a specific deficiency disease is produced on rigidly fat-free diets and is cured by the addition of certain unsaturated fatty acids. Vitamin B was definitely ruled out as a limiting factor in this deficiency. Corn starch and rice starch were effective in curing the deficiency, whereas potato starch was ineffective. The curative carbohydrates owe their effectiveness to their slight but important content in unsaturated fatty acids—presumably linoleic acid. Hog liver glycogen, whether prepared by hydrolysis with alkali or precipitation with trichloracetic acid, was ineffective.

Crystalline Vitamin D.—Bills and McDonald state that translation into international units of the potencies reported for several crystalline preparations of vitamin D reveals wide variation in antirachitic value. Under suitable conditions a resinous preparation can pass into the crystalline state without change of purity. The crystalline state is evidence of relative, not absolute, purity in vitamin D. The best crystalline preparations as yet described are probably isomorphous mixtures containing a large percentage of inert material.

Calcium and Phosphorus Studies: I.—Shelling reports that the calcium and phosphorus content of the diet is a determining factor in the presence or absence of tetany in parathyroidectomized rats. Low calcium or high phosphorus diets are conducive to parathyroprivic tetany, while high calcium or low phospharus diets are ameliorative. The serum calcium concentrations vary with the severity of the tetany and with the calcium and phosphorus intake. Cachexia parathyreopriva was found to depend on the food intake. Parathyroidectomized rats refuse to eat tetany-inducing diets and thus lose weight, but they consume optimal amounts of foods which relieve or prevent their tetanic manifestations. The anorexia was present when dietary phosphorus was in a form that could be utilized by the animal organism but absent when the phosphorus salts could not be utilized. Sodium metaphosphate and thiosulphate belong to the latter group. An analogy is drawn between the anorexia of parathyroidectomized rats on tetany-inducing diets and the vomiting of parathyroprivic dogs on similar rations. Attention is called to the importance of phosphorus as a factor in the study of parathyroid tetany.

Id.: II. Effect of Diet and of Viosterol on Tetany of Parathyroidectomized Rats.—According to Shelling, viosterol in fairly large doses is capable of raising the serum calcium levels and of ameliorating the symptoms of tetany of parathyroidectomized rats kept on very low calcium diets. Large doses of viosterol may raise the serum calcium of parathyroidectomized rats from tetanic to hypercalcemic levels, even in the absence of either calcium alone or of both calcium and phosphorus from the food. These experiments would seem to indicate that the activity of viosterol in raising the serum calcium levels may be independent of the parathyroids. The author discusses the relation of the parathyroids to the activity of therapeutic doses of viosterol.

Streptococcus Viridans Osteomyelitis.—Compere discusses the etiology of osteitis that is characterized by a fibroblast and giant-cell proliferation with bone destruction and new bone formation. He reports a case in which a strain of green-producing streptococcus grew in cultures of a lesion in the neck of the astragalus, which presented a microscopic picture similar to that of localized osteitis fibrosa without cyst formation. Clinically and bacteriologically it was a low-grade pyogenic infection and was classed as Streptococcus viridans osteomyelitis. He also reports a second case, which was clinically and pathologically similar to the first, except for bone proliferation, but in which the cultures were negative. That trauma may be a factor in localizing the infection is again suggested by these cases, but the opinion is expressed that reaction to trauma and hemorrhage could not alone account for the cortical absorption and the extensive new bone formation noted in the second case.

Trochanteric Transplantation in Fractures of Femoral Neck.—Jones summarizes the advantages of open operation by the trochanteric bone-graft method in fractures of the neck of the femur as follows: (1) early and accurate replacement of displaced fragments with assurance that no interposition of tissue exists; (2) bridging of the fracture line with an autogenous bone graft, providing firm internal fixation, the graft also acting as a source of calcium for the healing granulation tissue, and (3) early reestablishment of blood supply between the head and neck of the femur in an area where blood supply is minimal. He particularly emphasizes the conservatism of this method and the ease with which through a single incision the hip joint is widely exposed, an adequate bone graft is obtained from the trochanter as part of the operative approach, and the direction and position of the transplant are accurately determined.

Periarticular Innervation in Sprained Joints.—According to Brunschwig and Jung, the sensibility of a joint is primarily a periarticular sensibility, due to the abundance of nerve endings in the joint capsules and periarticular ligaments. In sprains, pain is due primarily to trauma of the periarticular innervation. Reflex muscular rigidity, involving the injured joint, also has its origin in the traumatized nerves of the joint capsule and ligaments. Periarticular injections of procaine hydrochloride have a definite therapeutic value in the treatment of sprains. With the pain and reflex muscular rigidity abolished, almost normal function is possible. In some instances the improvement is more or less permanent; in other cases several injections are necessary.

Congenital Dislocation of Hip.—A study of eighty-two open reductions of congenital dislocation of the hip, with a follow-up examination of seventy-two of the hips, is presented by Howorth and Smith, with details of the preoperative examination and treatment, the operative observations and procedure, postoperative care, and the results several years after operation. It is definitely shown that a fairly large percentage of congenital dislocations of the hip cannot be reduced, or the reduction maintained, by closed operation because of anatomic abnormalities about the acetabulum. It is further demonstrated that roentgenograms taken with the patient standing and under traction, as well as the ordinary recumbent views, are essential for a thorough study of these hips both before and after operation. It is particularly important that the pathologic condition and mechanism at the hip be carefully studied at operation. It is the authors' practice to study the hip at operation on exposure of the capsule, after opening the capsule, and after removing the ligamentum teres, to determine the factors interfering with reduction and stability, and they test the stability of the hip after reduction with upward pressure on the leg during gradual adduction and in various positions of rotation. The rotation procedure is valuable in determining the necessity for correction of anteversion. Furthermore, there is so much individual variation in these hips that they cannot be grouped together indiscriminately and compared superficially in attempts to present the best apparent results.

Longitudinal Fractures of Patella.—Lapidus calls attention to typical longitudinal fracture of the patella in a vertical sagittal plane, usually over the junction of the outer and middle fourths of the patella. This fracture is not as uncommon as is usually believed, but it is rarely recognized. Correct diagnosis of longitudinal fracture of the patella is important for the purpose of proper treatment, especially in legal cases. The clinical picture is clear cut: history of injury, localized linear tenderness over the lateral border of the patella, effusion in the knee joint (usually hemorrhagic), comparatively negligible disability. Special technic of roentgenography of the patella should be used in every case with these symptoms in which there is a suspicion of longitudinal fracture. Both knees should always be roentgenographed in order to differentiate the fracture from congenital anomaly of the patella. The therapeutic value of repeated aspiration of the effusion in the knee joint is emphasized in cases of longitudinal fracture of the patella. Longitudinal fracture of the patella may lead to a quite prolonged disability when overlooked. If properly recognized and treated, complete recovery within six to eight weeks may be expected. Operative treatment should not be employed in these fractures.

Pathogenic Bacteria in Feces.—Havens considers the detection of pathogenic bacteria in feces as one of the most complicated bacteriologic problems which a diagnostic laboratory encounters. Their isolation, in the first place, is attended by many technical pitfalls, and any significant organisms which may be found require intelligent and careful work for their identification. There are many intestinal bacteria which closely resemble the known pathogens but which so far have no definitely ascribed rôle. Their significance is uncertain and their presence is often confusing. Hence, one can hardly be too careful in the procedures used for purposes of identification. In the majority of instances, of course, such as typhoid, the offending organism is readily identified by comparatively simple cultural and agglutinative reactions. But when one approaches the paratyphoid group and, particularly, the dysenteries, skill and experience are needed. It is here, in this group of diseases, owing to their comparatively infrequent occurrence and their vague clinical symptoms, that the laboratory is called on to establish the diagnosis. Thus, even though such examples appear with comparative infrequency, it is nevertheless essential that the laboratory be prepared to make an intelligent examination.

Examination and Identification of Protozoa.—According to Faust, the protozoa found in human tissues and exudates include forms belonging to all four major groups of the phylum Protozoa, namely, the Rhizopoda, as illustrated by Endamoeba histolytica; the Mastigophora, as illustrated by the intestinal flagellates and the trypanosomes; the Sporozoa, as illustrated by the malaria plasmodia, and the Ciliata, as illustrated by Balantidium coli. Some of these organisms are strictly tissue parasites; others may be regarded as facultative pathogens, and still others are harmless forms of a coprozoic nature living in or passing through the intestinal tract. For purposes of convenience the author considers these protozoa under two categories, (1) those living in the intestinal tract and adjacent organs, and (2) those primarily involving the hematopoietic organs, blood stream and other body tissues.

Bacterial Mutations.—D'Herelle and Beecroft call attention to the fact that variations which occur among living beings may result, in general, from three different phenomena: 1. The existence of a life cycle such as one finds in the case of protozoa and insects. This phenomenon is easy to recognize, for it is cyclic; the variations are "ordinate." All the characters vary together as a whole. Moreover, in a species which has a life cycle, all the individuals suffer the same variation when placed in identical environments. 2. The adaptation to new external conditions. This phenomenon is not cyclic. One can produce easily such variations with bacteria when they are cultivated in what one might term "abnormal" mediums; but generally such variations are transitory. The character "sporulation" is the only one that undergoes a permanent modification after a strain has been cultivated or exposed to the presence of certain antiseptics. 3. Adaptation to new internal conditions. New internal conditions always result from the subjection of an organism to a parasite. Such parasitism is termed "symbiosis" when the host adapts itself to this new condition. This adaptation is always correlative to modifications of the characters of the host (as well as modifications of the characters of the parasite). The authors describe investigations which show that the principal cause of variations among bacteria is a result of a symbiosis and certainly not the result of a life cycle. The variations are not cyclic but appear in a disorderly fashion. What is more characteristic is that each character may vary by itself as an entity, without having any repercussive effect on the other characters. If one considers, for example, the three characters "virulence," "agglutinability" and "fermentation," one observes that there is no relation between the variation of one of them and the variation of the others.

Intact Intestine in Nonanesthetized Dogs as Affected by Anthraquinone (Emodin) Cathartics. C. M. Gruber, W. T. K. Bryan and L. K. Richardson, St. Louis.—p. 479.

Pharmacology of Metaphen and Acriflavine.—Crittenden reports that metaphen administered intravenously, except in enormous doses, does not have any effect on the blood pressure, heart rate and respiration of either barbitalized or unanesthetized dogs. In general, intravenous injection of therapeutic doses (0.15 mg. per kilogram) causes a marked leukocytosis, accompanied by a proportional increase in the different forms of leukocytes. In one dog out of ten a leukopenia resulted. It has no effect in similar doses on the fragility of erythrocytes. The minimum lethal dose of metaphen in dogs is 3.5 mg. per kilogram, which on the basis of its mercury content is equivalent to the minimum lethal dose of mercuric chloride. Certain preparations of acriflavine are definitely toxic, causing marked changes in the heart rate, circulation and respiration, and nausea and vomiting in intravenous doses of from 2 to 5 mg. per kilogram. A neutral preparation of acriflavine can be prepared which in doses of from 1 to 2 mg. per kilogram causes either no or only slight changes in the heart rate, respiration and blood pressure. The author believes that preparations of acriflavine should be tested on unanesthetized animals before they are used for intravenous therapy. Even the least toxic preparations of acriflavine in small doses stimulate and in larger doses depress the peripheral vagal mechanism in the heart. The author's results indicate that the chief point of action of acriflavine on the blood pressure is peripheral.

Experimentally Produced Convulsions.—Keith states that in rabbits the anticonvulsive effect of diacetone alcohol given by mouth is definite. A considerably larger amount of it is required than is required of phenobarbital to produce a similar effect. The latter, however, is much more toxic in larger doses and causes considerably more irritability to sensory stimuli. The anticonvulsive properties of diacetone alcohol depend on the acetone portion of the molecule.

Surgical Treatment of Pulmonary Tuberculosis.—According to Hedblom and Watterson, phrenic operations alone usually fulfil only partially the requirements of active treatment of tuberculosis, and they are inferior to other methods of collapse therapy, especially in their effect on cavities in the upper lobe; therefore phrenic exeresis as an independent intervention has only a limited application. Attention to certain symptoms is of value in handling cases. Thus, cardiac embarrassment following thoracoplasty due to air or fluid in the pleural cavity may be relieved by aspiration. Even if the heart can withstand any added load because of the collapsed condition of the chest wall and intrapleural air or fluid, the ultimate degree of chest wall collapse following thoracoplasty may be much interfered with. The authors believe that artificial pneumothorax treatment should last for at least two years unless it is complicated by adhesions, in which case major surgical procedures should be considered to maintain therapeutic collapse.

Spinal Anesthesia.—Roberts and his associates review a series of 518 cases of spinal anesthesias from the standpoint of age of patient, of type of operation, of risk, and of technic of administration, with a discussion of postoperative reactions and of the advantages and disadvantages of spinal anesthesia. No mortality attributable to the anesthetic occurred in this series. One standard technic, the Labat, was used throughout. A carriage convertible into several positions was used. The patient may be quickly put in the Trendelenburg position and transported in that position, which is of prime importance when spinal anesthesia is employed. While recent literature offers experimental evidence as to possible injury to the central nervous system and its coverings due to spinal anesthesia, clinically the authors have been unable to observe any permanent changes.

Early Diagnosis of Neurosyphilis.—Hubbs states that in the vast majority of cases at the time the first symptoms of neurosyphilis appear there are neurologic changes present which help to confirm a diagnosis of this disease. In the making of a diagnosis of neurosyphilis in the early stages of the disease a physician is aided by the fact that many such patients have positive blood Wassermann and Kahn reactions. Yet he must not consider neurosyphilis ruled out by negative blood reactions, since 8.8 per cent of a group of patients studied by the author had negative blood Wassermann or Kahn reactions at or near the time of onset.

Death Certificate and Causes of Death.—Crofton gives the following reasons why the facts as stated on the death certificate by the attending physician may be of the greatest legal and social importance: 1. Pensions or life insurance may depend on proper evidence of the facts and cause of death. 2. Certificates of death, or certified copies, are constantly required in courts and elsewhere to establish necessary facts. 3. Titles and rights to inheritance may be jeopardized by the failure of records. 4. Deaths should be registered so that public health agencies—national, state and municipal—may know the causes of death and act promptly to prevent epidemics. 5. Deaths should be registered promptly in order that the success or failure of all measures attempted in the prevention of disease may be accurately determined. 6. Deaths should be registered, that individual cities and localities may learn their own health conditions by comparison with the health condition of other communities and determine thereby the best courses of public activity. 7. Deaths should be registered, that homeseekers and immigrants may be guided in the selection of safe and healthful homes.

*Radium Poisoning. F. B. Flinn, New York.—p. 446.

Radium Poisoning.—Flinn states that, when radium is absorbed into the body, the immediate surrounding tissue is subjected to a bombardment of alpha and beta particles as well as to gamma rays. These alpha and beta particles are destructive to tissues under certain conditions. The alpha particle is the most powerful physical agent known to man. The change in the blood picture is due to the action of the radium on the bone marrow and lymph nodes. Anemia and drop in white cells finally result and the drop in white cells may indicate the terminal end. The blood picture in human beings varies somewhat during the clinical history and in individual cases, so that there is no characteristic radium blood picture. Anisocytosis, poikilocytosis and nucleated red cells are frequently seen. The radium tends to cause the cells of the body to revert to the primitive cells, as is seen on histologic examination of tissues. A certain percentage of cases terminate in sarcoma, generally those in which small amounts of radium have been present over a long period of time. Because the blood picture is unreliable for the detection of radium poisoning, dependence must be placed on the electroscope. In the treatment of the condition, operations are contraindicated. In jaw cases the wound should be kept draining as freely as possible. Liver, iron injections and blood transfusions do not produce any permanent improvement in the blood picture. The author has felt at times that the iron metabolism has been interfered with in these cases. His best results have been obtained by having the patients eat fruits, especially stewed apricots, which are high in iron and copper. High calcium therapy is indicated except when elimination is attempted. If the patient is kept on from 20 to 30 drops of viosterol three times a day, there is an elimination over a long period of time. The difficulty lies in the fact that one is dealing with an already damaged bone condition and that any intensive treatment will further decalcify the bones which lack the ability for regeneration.

*Trachoma and Trachoma Prevention Work in Missouri. C. E. Rice and J. E. Smith.—p. 888.

Trachoma Prevention Work in Missouri.—Rice and Smith report that the incidence of trachoma in Missouri seems much higher in the southern part of the state than in the north. One area in southern Missouri of 2,506 square miles shows a trachoma incidence rate of almost 20 per thousand. The probable percentage of trachoma blind in Missouri under the present legislative definition of blindness is 3.9 per cent of the total number of trachoma cases. Of 3,893 trachoma cases seen, 65 per cent were in males. Of 1,154 complete records studied, 88 per cent showed the presence of pannus involvement of the cornea. There was corneal damage sufficient to bring vision down to 20/200 or worse in both eyes in 12.5 per cent of all cases seen. Of 1,148 individuals hospitalized at Rolla, 7.1 per cent have been hospitalized three or more times. The authors estimate that there are 17,000 active and inactive cases of trachoma in Missouri at the present time.

Myopathic Family.—Barnes describes a variant of myopathy, occurring in many members of a single family, which passed through four phases—hypertrophic, pseudohypertrophic, atrophic and terminal—the last stage being associated with a distal atrophy of the upper extremities. Other clinical characteristics were early loss of tendon reflexes, late onset and slow progress, an almost constant association with adipositas universalis, and a relative absence of abortive forms and of polymorphism. The author states that a large and increasing body of evidence is available, which goes to prove that myopathy (muscular dystrophy) is determined at the birth of the ovum and is derived as a factor or as factors inherited from one or both of the two gametes which form the zygote. In rare cases, a new mutation (variation in a normal gene) may arise and be the cause of the condition in the individual developed from that zygote and be transmitted to his descendants. As to whether the effects of the mutant are manifested directly during the development of the individual, or indirectly through the endocrine glands, has not been established. The frequent association of myopathy with adiposity and other evidence of endocrine imbalance may be interpreted on strictly genetic lines, the hormone disturbance being a secondary effect of the mutant. In those cases in which microbic disease, trauma, overwork, and so on, are antecedent in the history, they are merely factors which determine the onset or accelerate the progress of the disease in an individual who is a potential myopathic, i. e., a genotype carrying the mutant gene or genes. Apart from the presence of such underlying factors, it is probable that the muscular dystrophy can never arise.

Familial Periodic Paralysis.—Maclachlan reports six cases of familial periodic paralysis in three generations of one family and reviews the histories of families previously recorded as suffering from this disease. The condition tended to develop about the age of 17 to 18 years in each member of the family, and in some patients who have suffered from paralytic attacks for years there was a development of permanent muscular weakness and rarely the picture of one of the muscular dystrophies; the occurrence of muscular dystrophies in other members of the families, who were not themselves affected by periodic paralysis, is also described. The condition is compared with migraine, epilepsy and certain heredofamilial degenerative diseases. It is considered that two factors are concerned in causing the attacks of paralysis, namely, (1) an abnormal constitution of diathesis in which there exists, in patients with a neuropathic inheritance, a condition of disequilibrium of the vegetative nervous system with evidence of periodic intoxication associated with abeyance of the digestive function and abnormal metabolism at the time of the attacks, and (2) some abnormality in the muscles themselves. The author believes that the attacks of paralysis are caused by the low resistance of the defective muscle to abnormal metabolic products present during the periods of intoxication, while it is probable that interference with the blood and lymph circulation in the muscles, which results from the disturbance of the sympathetic system, is a contributory factor.

Tonic Pupils and Absent Tendon Reflexes.—Adie states that the tonic pupillary reaction, under a number of different names, has been known to ophthalmologists since 1902. In some of their cases absence of one or more of the tendon reflexes was noted, but this was misconstrued as further evidence that the ocular signs were due to syphilis. The author's conclusions are based on a study of nineteen cases presenting tonic pupils, thirteen of them with absent tendon reflexes, that have been reported, almost all, in journals of ophthalmology. The cases showing tonic pupils and absent reflexes are tabulated. The disorder manifests itself in complete and incomplete forms. The complete form is characterized by the presence of the tonic convergence reaction in pupils only apparently inactive to light and absence of one or more of the tendon reflexes. The term incomplete forms is used for cases presenting (1) tonic pupillary reactions alone; (2) atypical phases of the tonic pupil alone (usually mistaken for iridoplegia or internal ophthalmoplegia); (3) atypical pupils with absent tendon reflexes, and (4) absent tendon reflexes alone. The tonic pupillary reactions are described in detail and discussed in relation to the Argyll Robertson phenomenon, fixed pupils and internal ophthalmoplegia. The conclusion is reached that the tonic pupil is essentially different from them. The features that distinguish it from the Argyll Robertson pupil are emphasized. The incidence and distribution of tendon areflexia are given and the general features of the disorder are described. The age of onset cannot be determined; females preponderate largely; the cause is unknown. The disorder runs a benign course and rarely causes trouble. Occasionally, vision is affected by defective accommodation. Evidence is adduced to show that the disorder is unrelated to syphilis. Under differential diagnosis, syphilis, the ocular manifestations of diphtheria and epidemic encephalitis are mentioned only to show that they never produce the symptoms found in this disorder. Other conditions are referred to in which the tendon reflexes are lost temporarily or permanently in the absence of disease of the spinal cord or peripheral nerves. The conclusion is reached that the symptoms described are the manifestation of a disorder of the sympathetic nervous system. They are the expression of a kind of perversion of nervous activity of which at present one can form no conception.

Simultaneous Alopecia Areata in Two Brothers. H. Goodman and H. S. Abel.—p. 198.

Significance of Erythema Nodosum.—Symes feels certain that persons who have been suffering from erythema nodosum are peculiarly liable to develop an acute and often fatal form of tuberculosis within six months of the illness, the most common forms being pleural effusion and acute general tuberculosis. In a series of cases of erythema nodosum which he reported three years ago, tuberculosis appeared within six months in 10 per cent: general tuberculosis developed in two, mononuclear pleural effusion in five, and tuberculous meningitis in one. A tuberculous pleural effusion developed in one other patient in this series, but this was five years after the attack. Since the reports of these cases were published, the author has seen thirteen cases of erythema nodosum; two of the patients, subsequent to the attack, have been found to be suffering from phthisis and have gone to sanatoriums for treatment. An attack of the acute specific fever, erythema nodosum as distinct from the allergic rashes of erythema multiforme or sepsis, calls for a prolonged period of treatment and after-care in order that the tragedy of a fatal attack of tuberculosis may not supervene. The author believes that the practitioner who neglects this precaution is as blameworthy as the man who is content in a case of syphilis to stop treatment as soon as the secondary rash has disappeared.

Lymphopathia Venereum.—According to Wolf and Sulzberger, lymphopathia venereum is not generally accepted as of venereal origin. Without careful examination, the primary lesion is often so insignificant that it passes unobserved. The penile lesion makes its appearance from ten to thirty days after infection and is followed by swelling of the inguinal lymphatics within a period ranging from two to three weeks. The onset is an insidious one, since the lymph nodes are indolent and, as a rule, cause little discomfort. With enlargement there is the tendency for these nodes to become conglomerate, and the overlying skin becomes markedly adherent, attenuated and of violaceous hue. As the disease progresses the lymph nodes soften; they begin to fluctuate, and eventually multiple fistulas appear which discharge a purulent yellowish fluid. Only about 50 per cent of the cases go on to this stage of fistulization. Not infrequently the iliac lymph nodes are involved and are then distinctly palpable, yet not tender. These nodes usually go on to resolution, and many of the inguinal ones likewise subside without treatment. In addition to the signs mentioned, which occur most frequently in males, esthiomène, or ulcus chronicum elephantiasticum vulvae, the condition known as "syphiloma" anorectale and a certain type of high rectal stricture, especially in women, have in many cases been proved to be part of this disease and are probably due to the same (unknown) etiologic factor. Any one of these manifestations, or a syndrome of two or more of them, can be present. Moreover, some cases of elephantiasis of the penis and scrotum are probably due to the same cause. In 1925, Frei introduced a specific intracutaneous test for lymphogranulomatosis inguinalis which has proved to be of distinct value in the diagnosis of conditions involving the inguinal lymph nodes and has been of great help in the classification of this group of diseases. Climatic bubo, strumous bubo, tropical bubo and nonvenereal bubo are all names that have been applied to conditions with this clinical picture, and many of these cases, with the aid of the Trei test, have been proved to be lymphogranulomatosis inguinalis. It is probable that, as the use of this test becomes more widespread, many of the foregoing names will gradually be eliminated from the nomenclature. The authors suggest the name "lymphopathia venereum." Besides the clinical condition described by Nicolas, Favre and Durand, this designation will then include those cases of esthiomène (ulcus vulvae chronicum elephantiasticum), of "syphiloma" anorectale, of elephantiasis of the penis and of rectal stricture, which, by means of the Frei test, have been proved to have the same etiology. All these conditions are due to disease and obstruction of the lymphatics following venereal infection and are probably due to the same etiologic factor or virus.

Nature and Treatment of Adiposalgia.—According to Jansen, "subcutaneous fatty infiltrations" is a term applied to cases in which, in certain parts of the body, there is a somewhat large amount of fatty tissue, very tender to touch and accompanied presumably with abnormal changes. The sites of choice are the legs, the medial surface of the knees, the hips, the abdomen around the umbilicus and along the curvatures, the shoulders (deltoid region), and the back of the neck. Here the tissue is more firm than normal and is unyielding to pressure of the fingers—not infrequently being described as "hard as a board." If one tries to lift up a fold of this tissue, either it will be impossible or—if it can be done at all—the fold is remarkably thick in comparison with the subcutaneous fatty tissue in other areas. On continued palpation, preferably in the form of massage with the skin well greased, one finds also changes in the structure of the tissue. These may be palpable as a large number of small, hard nodules varying in size from a grain of sand to a buckshot, packed more or less closely together. In some places the diffuse infiltration is the dominant form, in others the granular. The skin over the infiltrated areas may be tense and shiny, though as a rule it looks normal, but on rubbing or scratching it shows remarkably strong vasomotor reactions, redness and blebs. Fairly vigorous manipulation of the infiltrated tissue readily produces ecchymoses. The most important feature is the extreme tenderness to touch of the "infiltrated" area. Among the subjective phenomena are a certain unrest in the affected region, sometimes paresthesia, as formication, and frequently a sensation of cold or mere chilliness. When the fatty layer is very abundant, the skin is usually cool to touch.

Treatment of Nasal Infections.—Deck states that in the treatment of nasal infections by the super-Kromayer lamp the patient should be placed in a dental or similar adjustable chair. The head-rest should be one that can be tilted in any desired position. In the absence of such a chair, the patient may be placed in a semirecumbent position on a couch. The nose, if hypersensitive, must be sprayed with a 10 to 15 per cent solution of cocaine. A flat quartz applicator about 2 inches long, and rounded at the end, is next gently inserted into the nostril and pushed slowly up the nose as far as the patient can bear it, while the lamp is kept as nearly horizontal as possible. With a standard lamp, an application of from forty to sixty seconds is then given to each side of the nose. When this is done, the short quartz applicator should be replaced by one about 4 inches long, with flat sides and slightly curved at the end, so that it can be readily passed along the lower nasal passages. By gentle handling and accommodation to the curves of the lower nasal passages, this applicator can be easily passed almost into the nasopharynx. When this is accomplished, a similar exposure of from forty to sixty seconds may be given to each side. Treatment as a general rule should not be repeated for at least four days.

Treatment of Traumatic Lumbago by Manipulation.—Romer calls attention to the fact that the history in cases of traumatic lumbago tells of some definite though frequently slight sprain of the back, requiring perhaps only a few days' treatment for apparent recovery. Instead of perfect recovery, the pain, though rarely severe, never quite disappears, and as time goes on it becomes more persistent. Good results can be obtained by treatment based on the assumption that the condition is due to some adhesions in the muscular or tendinous structure of those parts. On examination the lumbar muscles will often be found wasted, while those on the affected side are usually rigid and contracted, and it may be assumed that it is here that some matting of muscles or adhesions among the deeper tendons exist. Normal mobility is frequently much impaired. Bending the trunk forward will often show that flexion in the region is deficient and not infrequently accompanied by pain. As a rule these cases are unilateral, and consequently lateral movements of the trunk are often impaired. In this condition, treatment aims at stretching the contracted muscles and rupturing any possible adhesions. An anesthetic having been given, the method employed is this: With the patient flat on the back, the leg on the sound side is flexed at the knee and the thigh flexed on the body till the knee touches the chest wall. It is then brought back to the extended position. The leg on the affected side is now put through the same movements, and comparison can be made as to the difference in resistance, which sometimes is most noticeable. Both legs are now brought up together, and both knees should be kept pressed against the chest for about a minute. The legs having been brought to the extended position once more, the patient is now raised to a sitting posture. The operator places one hand firmly on the affected side, while with the other he thrusts the patient back on to the couch; the hand in the middle of the back, acting as a fulcrum, causes extension; the trunk is then moved laterally on the pelvis. By these movements, full extension and flexion of the lumbar region is obtained. Pain rarely follows these manipulations, and greater freedom of movement is often experienced immediately afterward; but too much importance cannot be attached to the after-treatment. This consists in radiant heat and skilled massage performed daily for a period of about twenty minutes, commencing with light kneading, which can increase in depth as time goes on. Anything like roughness or deep pummeling is to be deprecated. Within the course of about four days, graduated exercises by means of weights and pulleys should be undertaken in addition to the massage.

Surgical Treatment of Diseases of Gallbladder.—Rowlands believes that as a good general rule it is wise not to operate during an acute attack of colic, jaundice or fever. It is safer to wait for a quiet interval, using the time to investigate and to prepare the patient carefully. Later, a more radical operation can be safely performed. Fortunately the acute symptoms usually subside under complete rest and careful medical treatment, for, unlike the appendix, the gallbladder and bile ducts rarely set up spreading peritonitis. It is true that occasionally the acute symptoms do not abate but get worse and demand emergency operations. Usually these should be limited to drainage of the gallbladder or common bile duct. Radical operations can, if necessary, be carried out later, when the patient is better, the liver functions are restored, and sepsis has subsided. It is a great mistake to let many recurrences take place or to allow time for dangerous complications to develop or the general health to become seriously depreciated. Too long watching and waiting and relying on drugs and dieting for the relief of symptoms inevitably leads to much suffering and a greatly increased mortality from delayed operation. Some of the consequences of delay are: (1) gangrene, suppuration and perforation of the gallbladder with local or even diffuse peritonitis, pylephlebitis, septicemia and multiple arthritis; (2) extension of the disease to the common bile duct with jaundice, infective or suppurative cholangeitis, with risks of hemorrhage and cholemia; (3) extension to the pancreas, causing either acute hemorrhage or chronic pancreatitis, with or without jaundice; (4) intestinal obstruction by gallstones ulcerating through into the duodenum or colon; (5) adenoma, papilloma and cancer from chronic irritation of the gallbladder and bile ducts; (6) cardiac degeneration from chronic septic absorption (the damaged heart is often restored by removal of a septic gallbladder), and (7) cerebral toxemia, from the same causes, which may induce mental confusion, depression and even insanity, which are sometimes overcome by removing the septic source of poisoning. Cholecystostomy affords complete and permanent relief of symptoms in only about 45 per cent of cases. The persistence or recurrence of symptoms is often due to stones left behind, to the persistence of inflammation in the walls of the gallbladder, or to the formation of new stones. Secondary cholecystectomy or choledochostomy is often required. Cholecystectomy affords complete and permanent relief in about 86 per cent of cases. The more accurate the diagnosis and the more complete the operation, the better the result. Some temporary recurrence of symptoms may follow cholecystectomy, owing, perhaps, to spasm of the sphincter of Oddi, with dilatation of, and inflammatory changes in, the bile ducts secondary to loss of the gallbladder. Under these conditions, spasmodic pains may develop and be attributed to stones left behind in the common bile duct. In the author's experience these symptoms are almost limited to late cases in which delay before removal of the gallbladder has already allowed infection to spread to the common bile duct. Cholangeitis may then persist or recur, perhaps with exacerbations, even after drainage of the common bile duct, as well as after the removal of the gallbladder. Medical treatment will generally cure these symptoms and should be well tried before one submits the patient to another operation, which may not discover any stone or obstruction in the bile ducts. Recurrence of symptoms after operation may be due to residual infection in the liver or pancreas, to stones overlooked in the ducts, to errors in diagnosis—such as overlooking ostearthritis of the spine—or to spastic or mucous colitis.

Duodenal Ulcer.—On the basis of an investigation of the records of 250 cases of probable duodenal ulceration, Morley draws the following deductions: 1. The sex incidence shows a preponderance of 5.2 males to 1 female. 2. One third of all patients first notice symptoms between the ages of 20 and 29; more than one half between 20 and 39 years of age. 3. The asthenic type of stomach is infrequently the seat of duodenal ulceration; but otherwise duodenal ulcers occur in the hyposthenic, sthenic and hypersthenic types in about the same proportions as these types occur in a hundred normal individuals. 4. The average test meal curve is higher in cases of duodenal ulceration than in normal individuals. 5. The curve of gastric acidity steadily increases from being lowest in the asthenic to a maximum in the hypersthenic type.

Paroxysmal Tachycardia in Pregnancy.—The noteworthy feature of a case of paroxysmal tachycardia observed by Anderson in a woman, aged 22, is that throughout the entire period of gestation not a single attack occurred. Apart from some sickness after meals, especially at night, she was perfectly well during pregnancy. The last menstrual period and the first after delivery were each associated with a paroxysm. An attack that appeared one week post partum, lasted over five and a half days, and the worst from which the patient had suffered, far surpassed in duration her previous record, which was thirty-six hours. One cannot fail to be impressed with the absence of tachycardia during the period of pregnancy, when many organs are overtaxed. One naturally wonders to what extent endocrine activity (known to be so pronounced in pregnancy) was concerned.

Hemolytic Streptococci in Infective Disease.—Okell believes that a large number of hemolytic streptococci from the most diverse sources in human disease and also from apparently normal persons are essentially similar, having the same general morphologic and biochemical properties. Agglutination tests, while they show that serologic differences exist among members of the group, do not differentiate species within the group. There are three properties characterictic of the pathogenicity of the hemolytic streptococci and these must be considered separately. 1. An erythrogenic (or rash producing) toxin, immunologically identical whatever the source from which the strain is derived. To this a neutralizing serum is available, under the name of "scarlatinal antitoxin." 2. A pyogenic property, common to all hemolytic streptococci and perhaps closely related to streptococcal hemolysin. To this no antibody has so far been discovered. 3. An invasive property which may or may not be linked with the pyogenic property. To this also there is no general antibody available, though Lancefield's and Todd's work suggests that antibodies to any particular strain could be prepared. These three elements in the attack of the hemolytic streptococcus, pyogenicity, toxigenicity and invasiveness, vary in intensity from case to case. The strength of the host's defense against erythrotoxin and the side of the conflict also vary. These differences are sufficient to account for the variegated pathologic and clinical patterns of human streptococcal disease. If these views are accepted it must be admitted that the hemolytic streptococci ordinarily encountered in disease constitute a species both on grounds of formal taxonomy and of pathology. With regard to the nomenclature of the species, Rosenbach's term Streptococcus pyogenes has the unquestionable right of priority; hence it should replace Schottmüller's term Streptococcus hemolyticus, which at present seems to have the greater vogue. It would be quite unjustifiable to predict that other species of hemolytic streptococci will not be established in the course of time. For example, the position of the so-called Streptococcus epidemicus and certain hemolytic streptococci found in animals have not yet been clearly defined. The anaerobic hemolytic streptococci have also to be given their proper position. But in the light of present knowledge there is little doubt that it would save much confusion if bacteriologists would abstain from putting forward new species without good reason, and from what is almost worse—giving pseudospecific names to what they would never themselves claim were species in any strict biologic sense.

Gallbladder and Cardiac Pain.—Miller calls attention to the fact that clinically there may be considerable resemblance between the severe pain of the gallbladder and cardiac pain, and there may be overlapping of symptoms in severe attacks affecting either organ. Both types of pain can occur in the same subject and be recognizable as distinct. Disorders of both organs may be present in the same patient. Cases have been quoted in which surgical treatment of the gallbladder has been followed by relief from both types of pain. If there is any reason to suspect the gallbladder in any patient who has cardiac pain, a full investigation of the gallbladder should be made, and if sufficient evidence is found, operation should be advised. A study of morbid anatomy reveals the fact that in subjects with diseased gallbladder the degree of arterial degeneration was higher and the cases of severe arterial degeneration were more numerous than in those whose gallbladders were healthy. That being so, it would appear to be rational to deal thoroughly with cases of cholecystitis or gallstones as soon as diagnosed.

Cardiac Arrhythmias.—Hoskin states that cardiac arrhythmia is not uncommonly found in cardiovascular syphilis; it may show itself in the form of ectopic beats, as auricular fibrillation, or as an impairment of the conductivity of the neuromuscular system. Thus, all forms of auriculoventricular block may be found as the result of syphilis. The author emphasizes the necessity of obtaining a full history and of having Wassermann and Kahn tests done in all cases in which the integrity of the cardiovascular system is open to doubt. Syphilis, unlike rheumatic fever, affects not only the heart muscle but also the proximal part of the aorta, with involvement of the orifices of the coronary arteries, resulting in a condition of anoxemia of the heart muscle. Patients with cardiovascular syphilis stand operations badly, and therefore a positive Wassermann reaction or signs of cardiovascular syphilis makes the operative risk much greater, and it is thus of the utmost importance that the surgeon and anesthetist should be cognizant of it prior to the operation.

Brucella Infection in Chinese.—Zia and Wong report two cases of undulant fever of natural infection and one of probable laboratory infection. They were all proved by positive agglutination and blood culture. An attempt to differentiate the organisms obtained into the subgroups of Brucella was made and the common differential tests are briefly described. Incidence, symptomatology, diagnosis and treatment of this disease are briefly discussed. Attention is called to the present lack of definite knowledge in the spread of this disease in North China, where dairy products probably do not play an important part.

Gastric Secretion in Vitamin A Deficiency.—Pillat and Chang studied the gastric function by the histamine method in twenty-five cases of vitamin A deficiency. A definite depression of the acidity was found in ten cases. Four patients had anacidity. The degree of impairment of the gastric function seemed to be related to the duration and severity of the eye disease. After the administration of cod liver oil and improvement of the eye lesion, in seven out of the eight cases reexamined the patients showed an improvement in the gastric secretory function.

Renal Tuberculosis.—The results of a survey of fifty-six new proved cases of renal tuberculosis seen during the past ten years are summarized by Shih and Char as follows: Renal tuberculosis was seen in the male almost three times as often as in the female. It occurred most frequently in the second, third and fourth decades of life. It affected people of all professions, most commonly students, merchants, housewives and soldiers. The two kidneys were affected with equal frequency. Evidence of tuberculosis in other parts of the body was found in 35 per cent of the cases. The general health of the patients was good in 50 per cent of the cases. Sixty per cent of the cases were seen within the first year of symptoms. The symptoms in the order of their frequency were hematuria, frequency of urination, painful urination, pyuria, and renal and vesical pain. The urine was acid in 75 per cent of all the cases and contained albumin in 88 per cent. Tubercle bacilli were demonstrated microscopically in 27 per cent, in catheterized specimens from separate ureters in 36 per cent and by guinea-pig inoculation only in 9 per cent — a total of 72 per cent. The advantages of cystoscopy, ureteral catheterization, roentgen examination and pyelo-ureterography are discussed. The authors believe that renal tuberculosis is never cured by general medical and hygienic measures alone. Nephrectomy, wherever possible, is the treatment of choice. Fifty-five per cent of the cases were operable. There was no immediate operative mortality in this series. Fifty-five per cent of the patients in whom nephrectomy was performed are greatly improved or well.

Resection of Cellular Tissue in Treatment of Paronychias.—Rougemont and Carcassonne state that, in a large number of cases of infection of the fingers, simple incision is not enough to assure cure, because there is not an actual collection of pus but a necrosis of cellular tissue, elimination of which is slow. A large resection extended into the healthy tissue in rapidly removing the contaminated zone has incomparable advantages over incision: it hastens cicatrization in all cases, it avoids the silent spread of infection, which often persists after the usual treatment; finally, although extensive, it permits preservation of the finger with satisfactory function in cases in which its vitality was endangered. In reviewing the pathogenesis of panaris the author calls attention not only to the extensive tissue necrosis but also to the severe inflammatory reaction which accompanies it and which in the finger, owing to its construction, can lead to great detachment and extensive gangrene of the skin and consequent amputation. By simple incision with a bistoury one may sometimes cure a beginning cellulitis, but more often the lesions are too serious and following incision the cellular tissue ruptures, drainage is impeded or lacking, tumefaction is increased, and there persists for weeks a state of semiinfection, which leaves the affected area much altered. The thin cicatricial tissue that replaces the necrosed skin adheres to the decalcified bone without interposition of cellular tissue. Excision of the entire zone of infection at the start avoids its extension and also reduces the severity and intensity of the inflammatory reaction and its dangers. The authors think a large excision with scissors which, while sparing the nerves, vessels and sheaths, removes the diseased tissue and extends just into the healthy tissue constitutes an efficacious therapeutic measure.

Treatment of Primary Syphilis by Inoculation with Spirochetes of Rat-Bite Fever.—Hashimoto and Iwakiri report the results of treatment in thirteen cases of primary syphilis by inoculation with the spirochetes of rat-bite fever (Spirochaeta morsus-muris). While they admit that their material is insufficient for a definite judgment of this therapy, they conclude that primary syphilis may be completely cured by inoculation of rat-bite fever, without other treatment. The patients were inoculated intramuscularly with spirochetes obtained from the blood of guinea-pigs that had been inoculated with cultures of the organism. The rat-bite fever, which develops after an incubation of from six to sixteen days, may be intermittent or continuous. The rat-bite fever was cured by injection of arsphenamine after the second or third attack of fever. The quantity used was as small as possible (from 0.3 to 0.4 Gm. every three to five days, to a total of from 0.6 to 1.5 Gm.) to avoid influencing the syphilitic treatment. Inoculation of the rat-bite virus resulted in the disappearance of Spirochaeta pallida from the chancre in the first days of fever even in cases in which a great many spirochetes had been observed previously. In one case the spirochetes disappeared from the chancre before the fever attack. Serum reactions (Wassermann, Meinicke and Murata) were practiced before and after inoculation, after each fever attack, and after each injection of arsphenamine. The serum became negative and remained negative in six of the nine cases observed sufficiently long. In two of the others there was a decided decrease in the strength of the reaction. In the control case, in which an injection of arsphenamine was not given, the serum reaction became quite strong from time to time but became completely negative after one year. In discussing the disappearance of Spirochaeta pallida from the chancre, the authors advance the idea that this may be due to the reproduction of Spirochaeta morsus-muris, which is antagonistic to Spirochaeta pallida, instead of being due to the fever caused by the rat-bite virus.

Generalized Thoracic Pulsation.—Padilla and his collaborators consider the diagnostic value of a sign (previously described by Arrillaga and Dabove) as pathognomonic for aneurysm of the retrocardiac portion of the descending aorta (even in cases in which the small size of the aneurysm or its location behind the heart make it difficult to diagnose by roentgen examination). The sign consists in a generalized pulsation of the entire anterior aspect of the thorax, which is synchronous with the ventricular systole and during which the two halves of the thorax present an opposed pulsation; that is, an elevation of the left half of the thoracic anterior wall with a simultaneous depression of the right half. However, the authors found the sign in three cases with some pathologic conditions of the heart (cardiac hypertrophy and tumors behind the heart), while it was absent in a case of aneurysm of the retrocardiac portion of the descending aorta. From their observations in the cases mentioned, the authors conclude that the sign of generalized thoracic pulsation may appear in aneurysm of the retrocardiac portion of the descending aorta, in tumors located behind the heart, and in hypertrophy of the heart. The generalized thoracic pulsation is caused by the systolic dextrotorsion of the heart when this organ is imprisoned between the anterior thoracic wall anteriorly and the vertebral column posteriorly, owing either to its increased volume or to the space being occupied by aneurysm or tumor. The pulsation is caused by a thrust of the heart against the thoracic wall, which causes the elevation of the left half of the thorax with a generalized pulsation. When the precordial systolic elevation is followed by a second diastolic elevation caused by an impulse of the heart by the dilatation of the aneurysm, there is a double pushing of the heart against the thoracic wall (the first projection of the heart being caused by the apex beat while the second represents a renewed impulse given to the heart by the expansion of the aneurysm during the diastole), a sign which Hope described in 1830 under the name of "double jogging impulse."

*Injection Treatment of Inguinal Hernia. J. Marín Espinosa.—p. 405.
Gonorrheal Arthritis: Present Status. J. M. Tome Bona.—p. 409.
Surgical Treatment of Tumors of Spinal Cord. L. Dominici.—p. 411.

Injection Treatment of Inguinal Hernia.—Marín Espinosa obtained good results in 500 cases of inguinal hernia in adults from 40 to 80 years of age, with a treatment of about eight to ten injections, at weekly intervals, of from 0.5 to 2 cc. each of a solution made up according to the following formula: 80 Gm. of absolute alcohol, ten drops of solution of orthophosphoric acid, and as much distilled water as required to make 100 cc. In some exceptional cases he injected a larger dose (from 4 to 10 cc.). From his observations the author reaches the following conclusions: The treatment with stimulating injections is efficient when inguinal hernia may be easily reduced and the reduction maintained by a truss, regardless of the size of the hernial sac, its duration, its primary or recurrent development, and the age and general condition of the patient. The treatment is harmless and does not interfere with the working activities of the patient, since it is of an ambulatory type; no complications are observed during its administration and it is followed by complete recovery in 85 per cent of the cases. It is advisable to have children with inguinal hernia use a truss, with the use of which, as a rule, complete cure is obtained at that age. Young persons as well as more mature persons in good health should be operated on. The injection treatment should be reserved for the aged or for mature adult patients with some other coexistent diseases or poor general health. The author warns physicians to whom the technic of the stimulating injections for inguinal hernia is unknown against the use of commercial preparations which they received from abroad or from some other cities with instructions by correspondence to give the injections. The method, which in the hands of surgeons is safe, may be dangerous if given by physicians who are not familiar with its technic.
